DERMATOLOGY AS A SPECIALTY, AND ITS RELATION TO INTERNAL MEDICINE*

GROVER W. WENDE, M.D.
BUFFALO

It seems appropriate that my address, as chairman of the Section on Dermatology of the American Medical Association, should be devoted not so much to the refinements of a specialty as to the general and fundamental relations of this specialty to medicine as a whole.

One by one the individual branches of medicine have been cut off the main trunk and cultivated exclusively by specialists. This process of the division of labor was inevitable and indispensable for advance through concentration of effort. But, as in all restricted effort, the very concentration tended to narrowness of observation and loss of perspective that impaired the broadest utilization of the observations made, both for the specialist and for the generalist. The specialist became too much a specialist and lost a capacity for the correlation of the minutiæ of his observations into generalizations. The generalist—and I mean by the generalist the scientific internist as well as the general practitioner—on the other hand, was separated more and more in his understanding and interest by the complexity of the specialty. He not only could not follow the complications and intricacies of the specialties but he had little interest in them, in so far as they remained separated by failure to correlate them with their general causes.

These considerations apply with exceptional force to the specialty of dermatology, which alone concerns us at present. Dermatology has become so complicated with fine distinctions of terminology and classification that its underlying principles and fundamental relations have been much obscured by the haze of details that has enveloped it.

Is it not proper, therefore, that we as *dermatologists* should make some effort to bridge the ever-widening *separation between our specialty and the field of internal medicine?* Should we not attempt to interest ourselves more in the newer generalizations of medicine and to bring the internists into closer touch with ourselves and our work? I believe that this is becoming essential to progress. The period of infancy in our specialty is passing. This period has been devoted to *the collection* of simple observations and facts. This collection cannot be claimed to be completed and must be still further extended. But already the unrelated facts observed and brought together in the domain of dermatology are becoming cumbersome and an impediment to progress. Correlation of these facts must be attempted if confusion is to be avoided. General causes must be sought and discovered. We as specialists alone cannot undertake this difficult task. We must unite with the internists and together work in the clinic and the laboratory in the investigation of broad relations and causes.

With the exception of parasitic and local inflammatory affections of the skin and with the further possible exception of certain skin affections of wholly unknown nature, it may be said that skin diseases are for the most part simply the superficial local manifestations or complications of general or special morbid states involving the tissues of the body either generally or specially in certain organs or groups of organs. In short, most skin diseases are nothing but symptoms or complications of constitutional or special morbid states. This statement may appear at first sight too sweeping a generalization and perhaps somewhat of a prophecy, but of its essential truth I have been convinced the more I have given consideration to it.

If I am correct in this view, then my plea for more *systematic cooperation* between the dermatologist and the generalist is clearly supported. Not only is this cooperation of study demanded for the highest ends of scientific medicine but also for the many incidental advantages to all concerned in it. What needless distress and even disaster ensue to the patient by reason of the ignorance of the general practitioner as to the interpretation of many skin lesions. We as dermatologists are constantly reminded of this fact. Can we claim that the reverse is not also *true? How do we know that it is not?* With all our little distinctions and refinements of classification of skin lesions do we know much of the internal relations and final causes of these lesions? Do we know that a skilled internist may not discover related manifestations in other parts of the body and suggest therapeutic measures of value equal to or even greater than our own? It is true that, thus far, *the internist* has added little or nothing to such correlation, because he has failed to realize its value.

But far more important is the determination of new *facts, new relations, new conceptions, the simplification of complexity.* All these will come in time. We can hasten their coming by stimulating the interest of our fellow internists and working with them.

As dermatologists we should not be summoned to the *hospital clinics* occasionally and separately to inspect or diagnose an unusual skin affection; we should consult with the internist, give and take, and together learn. Cooperation of study between ourselves and all the departments of scientific research in our hospitals and laboratories should be instituted and systematically prosecuted. How else can dermatology be correlated with scientific medicine?

It is surprising to note the crude notions still prevalent among the laity and even physicians regarding skin affections. How much harm and needless suffering result from these false views! How many innocent persons are cruelly subjected to unjust suspicions of moral guilt, due to ignorance of the real nature of their skin affections! How frequently do we still encounter such old superstitions as the effect of "catching cold" and of psychic influences in producing all manner of skin diseases!

---

* Chairman's address before the Section on Dermatology of the American Medical Association at Its Sixty-first Annual Session, held in St. Louis, June, 1910.

The idea that skin lesions are manifestations of "impurities of the blood" and require "medicine for the blood" is too deep-rooted in the ignorance and prejudice derived from past teaching to be readily overcome. A natural variation of this view is seen in the notion very commonly held that some skin diseases should not be treated locally, lest they be "driven in." Other variations of the blood diathesis theory still widely held are the views that many skin affections are due to a scorbutic taint or to scrofula.

These are specimens of the theories formerly held by the medical profession and still deeply ingrained in the prejudices of the laity and in the ignorance of many practitioners. Other crude notions of a blood diathesis still persist within the profession, modified, however, to conform with newer conceptions of pathology but still running in the same old grooves. Thus the uric acid diathesis theory of skin affections is nothing but a modern setting of the older views. So long as nothing much was known about uric acid this theory satisfied and was dignified by a certain pseudoscientific assumption of exactness. This idea was handed on to the laity and is to-day one of the chief errors that we have to combat. With the passing of uric acid as a cause of every conceivable ill to which flesh and skin are heir, we shall presently, probably have other variations of the old dogma to contend with. That there may be an element of truth underlying these crude notions we may readily believe, for metabolism lies at the foundation of all vital processes and errors of metabolism may be presumed to account for many of the variations from normal in the different tissues and functions of the body. But in making this admission let us not again be led into the same old error of assuming to know the exact nature of such metabolic errors and of assigning to mere hypotheses the dignity of authority. This has been the trouble in the past and warns us of danger in the future. Let us keep in check our enthusiasm for new notions until we can see clearly. Let us contribute our part to the active research now being vigorously pursued in the study of faulty metabolism, but beware of crude generalizations based on incomplete data. Thus only shall we avoid falling victims to the temptation of easy conclusions based on shallow thinking.

But while striving for ideals in the scientific correlation of dermatology with internal medicine, the utilization of the practical knowledge already possessed should not be neglected. How much of practical importance can be contributed to-day by trained dermatologists to general practitioners? How slight is the understanding by most practitioners of the many lesions of the skin which they see! How often do these lesions give important clews to internal affections? The general practitioner must be far better trained in dermatology in order to comprehend and justly to estimate the relations of dermatology to general medicine. A much closer professional relation should exist between the dermatologist and the general practitioner for the good of both and of the patient.

In the short space of this address I cannot consider at length many of the numerous points of practical contact between dermatology and internal medicine, but I may refer briefly to some of them, chiefly for the sake of illustrating the shortcomings in practice resulting from a failure of intimate cooperation between dermatologists and generalists.

DISEASES ESPECIALLY CALLING FOR COOPERATION BETWEEN DERMATOLOGISTS AND INTERNISTS

Exudative Erythemas.—We have been accustomed to regard as belonging to the specialty of dermatology the several varieties of exudative skin lesions of the erythema group. Only within recent years has this whole complex group been correlated with important manifestations in the internal organs. An appreciation of this correlation is as essential to the dermatologist as to the internist and surgeon. Would it not be folly to treat the skin lesion and to overlook an acute nephritis, bronchitis, pericarditis, arthritis or abdominal complication? Are we, as dermatologists, accustomed to refer such cases for general examination? On the other hand, how rarely do the internist and the surgeon take account of the clew to diagnosis afforded by these lesions in cases presenting acute abdominal symptoms! Twice in a single week I have seen hospital patients barely saved from an unnecessary laparotomy by the timely intervention of physicians who fortunately did possess enough of broad training to embrace a knowledge of the correlation of such skin manifestations with acute abdominal symptoms and to advise against operation. Many instances of laparotomies actually performed for supposed appendicitis, intussusception, twists of the intestines, tumors and other abdominal conditions have been reported—and doubtless many more have not been reported—which could have been avoided by a knowledge of the correlation of such abdominal symptoms with exudative skin lesions of the erythema group. How long will this kind of one-sided specialism continue to the detriment of scientific practice?

Syphilis.—Of all diseases demanding the attention of dermatologists, specialists and generalists, syphilis is one of the most important, involving in its consequences not merely the health and life of individuals but the happiness of families and the welfare of society. This disease, which affects every tissue of the body and remains transmissible for years and perhaps through generations, first manifests itself by lesions in the skin and mucous membranes, for which the dermatologist is often first consulted. Later, the general practitioner is required to treat the disease for the involvement of internal organs, the neurologist for the late consequences on the nervous system, the surgeon for destructive changes in the bones and joints, and the other specialists in turn for the involvement of various organs. How important it is that this disease be understood in its broadest relations, its various manifestations mastered by all practitioners of whatever limitation in their field of work, and its proper treatment thoroughly comprehended! How far are we from this accomplishment! Dermatologists, by their unusual opportunities for observation of the skin manifestations of this disease, have acquired a skill in its diagnosis that is equalled by no other practitioner. Yet how frequently is our cooperation sought by our colleagues in their doubtful cases? In no other common disease is the penalty exacted for incorrect diagnosis and faulty treatment so severe.

Better education regarding the prevalence, manifestations, diagnosis and treatment of this disease is imperatively demanded. The general ignorance of the medical profession regarding syphilis is deplorable and a reproach that we should feel. A systematic campaign of education in syphilis might well be undertaken by the official organ of our association. To this end I would recommend that our Section take appropriate action.

Leprosy.—This is a disease fortunately rare in this country and for this very reason one that is usually mistaken for other affections, notably for syphilis. Most of its manifestations, however, are found in the skin or external portions of the body, rendering its diagnosis easy for those skilled in lesions of the skin. The training of the dermatologist especially equips him for the differentiation of this disease from those conditions with which it might readily be confused.

Pellagra.—This disease, which is now attracting so much attention and which has until recently been entirely overlooked in this country, would be readily recognized by any competent dermatologist by reason of the characteristic pigmentation of the skin.

Diabetes.—To a dermatologist such symptoms as slight, recurring inflammation of the prepuce, itching of the skin, ulceration at the base of a nail and furunculosis would at least arouse a suspicion of diabetes; the occurrence of certain skin lesions, xanthoma diabeticorum, would be almost pathognomonic. In diabetes early diagnosis and treatment are certainly important.

Punctate Telangiectases.—These little lesions, while often of no moment, are not infrequently observed in connection with cardiac and hepatic disease and should never be passed over as of no significance without examination of the internal organs.

Eczema and Psoriasis.—While these common affections cannot usually be definitely associated with internal disturbances, not infrequently they can be, and their occurrence should always suggest a careful general examination. Their correct treatment very frequently demands the treatment of the underlying or associated conditions.

Parasitic Skin Diseases.—These wide-spread and annoying diseases of the skin are usually treated by the general practitioner, who has very frequently failed to do his full duty toward them, by reason of incorrect diagnosis, careless methods of treatment and still more careless methods of enforcing personal and public hygiene and quarantine. Errors in any of these points may lead to epidemics that could have been prevented by the institution of proper measures at the outset. These diseases should be among those required by law to be reported and controlled by the public health authorities through the enforcement of suitable quarantine.

Eruptive Fevers.—No class of diseases is of such importance for the public welfare as these. Once started they become epidemic and a veritable scourge to the community. Their correct and early diagnosis is, therefore, vital to the protection of the public health. While the diagnosis is often well made by the general practitioner, how frequently is this not the case? Lack of sufficient instruction on these diseases in the medical schools leaves the young graduate poorly equipped to diagnose them. How many medical students ever saw a case of smallpox? What wonder is it, therefore, that in actual practice smallpox is rarely diagnosed until it has already become epidemic and disseminated far and wide?

Both smallpox and scarlet fever are diseases that very frequently appear in individual cases in abortive or anomalous forms, calculated to deceive all but the elect. The general practitioner must be on guard against making fatal errors of diagnosis in such cases and would receive a genuine service from the counsel of an experienced dermatologist when in doubt in his diagnosis.

Drug Eruptions.—The recognition of drug eruptions is important both for their relief and especially for their correct differentiation from more serious conditions with which they are likely to be confused. Imperfect knowledge regarding these common conditions has often led to the gravest diagnostic and therapeutic errors. For example, the coal-tar preparations so widely used often produce eruptions of most varied form and extent in the skin and mucous membranes. Such eruptions have frequently been mistaken for syphilis, lichen ruber, pemphigus, scarlet fever, measles, etc., and in consequence the patient has been subjected to the most unnecessary treatment and restrictions. The correct diagnosis in many such instances has been suggested only by the subsequent repeated occurrence of similar outbreaks of the skin whenever the particular drug has been taken. Every physician should be familiar with the possible cutaneous effects of the drugs which he prescribes, and this knowledge can be acquired only by a large experience and exact observation. These eruptions are as a rule well known to dermatologists and should offer little difficulty of diagnosis.

The relationship of the functions of the skin to those of internal organs are beginning to be fairly well comprehended, although many of the most important bearings are still poorly understood. The connection of cutaneous diseases with inflammation of the mucous membranes in some cases is of unusual interest. It is not uncommon for a patient to seek out a physician, bringing the information, during an acute attack of his eczema, that an asthma from which he has suffered shows amelioration, and *vice versa*.

There is another class of cases of skin involvement in which the underlying causes are vasomotor in origin, without recognizable heart lesions, although, in certain instances, the symptom of tachycardia may be present. These circulatory disturbances may be accompanied by a great variety of skin manifestations whose relations to them are as yet but poorly understood.

This list could be extended almost indefinitely, but my purpose will have been effected if the few illustrative conditions cited shall have helped a little to indicate some of the points of contact between dermatology and general medicine and to encourage a closer cooperation of study and effort among all. Our fields of work must remain more or less differentiated, yet should be united more and more by bonds of allegiance and common purpose in the pursuit of ideals in the science and art of medicine.

In the furtherance of these ideals more intimate relations should be cultivated among the special Sections in the meetings of the American Medical Association, so that each Section may have a greater educative influence on the whole body. With this end in view the program of our Section ought to be arranged to include subjects of general interest, that will instruct all. It is hoped that the slight attempt in that direction this year may be an inspiration for greater future endeavor.

It is gratifying to me to be the first to welcome this Section under its new designation of the Section on Dermatology. I am sensible of the great honor you have conferred in choosing me as your chairman, and desire to express to you my dutiful thanks and to assure you of my liveliest appreciation. I also wish to acknowledge my indebtedness to our Secretary for his proverbial zeal and energy in connection with the interests of the Section.

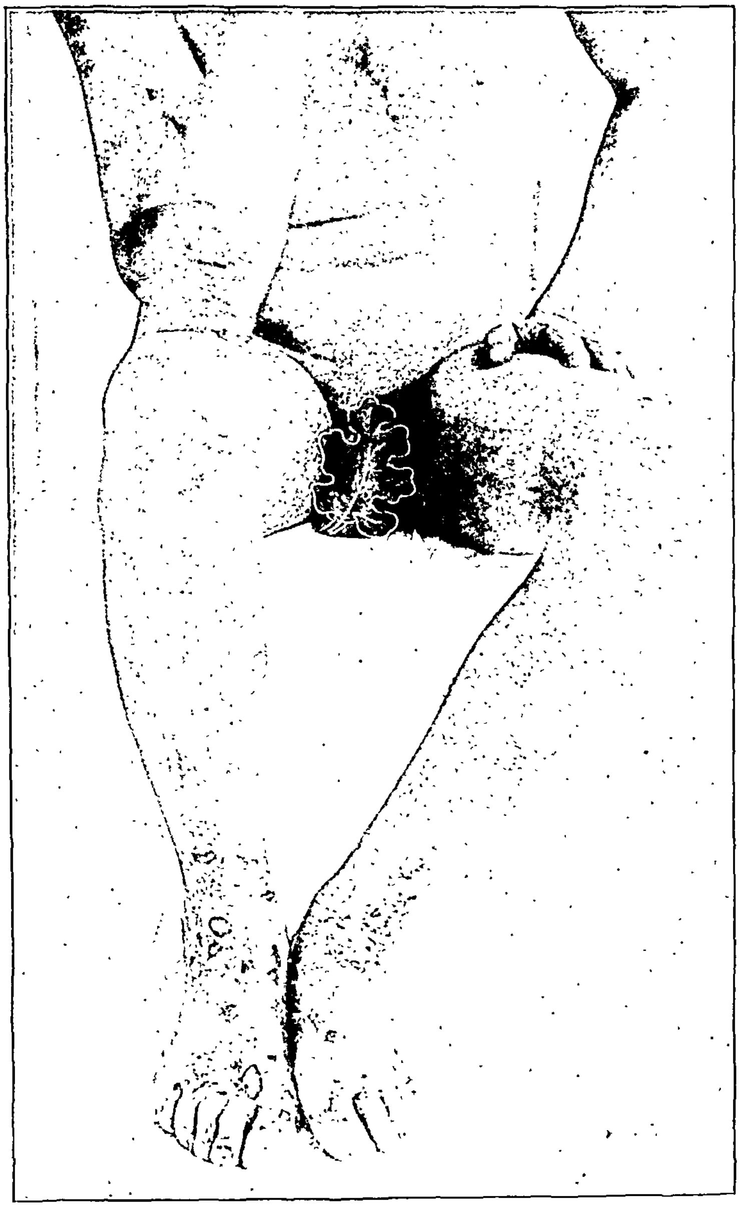
PEMPHIGUS FOLIACEUS

WITH REPORT OF A CASE*

ALFRED SCHALEK, M.D.
Professor of Dermatology, University of Nebraska
OMAHA

Pemphigus is a skin disease characterized by the eruption of blebs. These are, however, not characteristic in themselves but only in connection with other important features. The whole subject is not sufficiently cleared up yet and there is no unanimity as to what to include and what to exclude. Dermatitis herpetiformis is still considered pemphigus in Germany. Various skin diseases are denominated pemphigus, such as pemphigus neonatorum, which most probably is a bullous form of impetigo contagiosa, pemphigus syphiliticus, a manifestation of syphilis, pemphigus neuroticus and hystericus, sequels of functional and organic nerve disorders. A strict avoidance of these names would clear the ground rapidly. Bullæ are seen in bullous dermatitis, bullous erythema, and bullous urticaria, but nobody thinks of including these in pemphigus. Whether there is an acute pemphigus is a matter of controversy and denied by many.



Pemphigus foliaceus.

What then does constitute real pemphigus? In the first place the characteristic feature is the bleb, which must be elementary, that is must begin as such and not be due to secondary changes of other skin lesions. It must be the essential and not an incidental or unusual feature of the disease. It must not be a local condition, but the manifestation of a grave internal disorder. Its course is chronic, with exacerbations and remissions, leading to a deep systemic depression and frequently to death. With such restrictions it may easily be seen that many cases of pemphigus reported must be excluded from consideration under this head and that pemphigus as an idiopathic disease (called so in the absence of a better knowledge of its nature) is a rare disease.

Of the etiology of pemphigus nothing is known. Against a microbic theory speaks the fact that the contents of fresh bullæ are sterile; that there is no clinical evidence of its contagiousness; that not more than one case in one family has been reported. A toxic process was considered from the analogy of the action of certain poisons and drugs which, when introduced into the system, were followed by the eruption of blebs. The occasional increased percentage of eosinophils was used for this argument. Many attribute pemphigus to a neuropathic cause, arguing that some functional and organic nerve disturbances manifest themselves by the appearance of blebs. Numerous examinations of peripheral and central nerve tissues in autopsies have shown no pathological changes in them. Age, sex, race and climate have no predisposing influence. Riecke says very tersely, that our total ignorance of the etiology of pemphigus serves as a valuable diagnostic point in its differentiation from other bullous diseases.

Of the three varieties, pemphigus vulgaris, foliaceus and vegetans, the last two are the rarest. Pemphigus foliaceus, of which I wish to report a case, is clinically so different from pemphigus vulgaris that it might be considered a separate disease, were it not for the fact that they sometimes lapse into each other. Pemphigus foliaceus occurs only once in 5,000 skin diseases and Croker has only seen six cases in a life-time of extensive dermatologic practice. Pemphigus foliaceus is a chronic disease which breaks out in successive crops, until it finally involves the whole surface. The cutaneous lesions are flaccid bullæ containing only sufficient fluid to bag their dependent parts. The contents are cloudy almost from the first and soon become purulent. The blebs rupture quickly and the epidermis exfoliates in shreds leaving the corium denuded and moist. The raw patches are covered with a foul-smelling sero-pus and have no tendency to dry up and to be covered with a healthy epidermis. The exudation undermines the neighboring skin, giving it a shriveled appearance, and looks, as Cazenave says, like a flaky pie-crust. When the disease is fully developed, the body is covered with raw areas of various size, shreds of epidermis and loosened skin.

The mucous membranes may take part in the process, a complication considered especially unfavorable. The general health may not suffer at first, but the patient becomes ultimately cachectic or dies from an intercurrent disease. The end is almost always fatal, though sometimes not until after a few years.

The pathology of pemphigus has been thoroughly studied. The location of the bleb may be interepithelial or between the epidermis and the corium. The epithelial cells are edematous and swollen. The interspinous spaces are occluded. The corium is the seat of a mild probably secondary, inflammation. The papillary blood-vessels are dilated and surrounded by small mononuclear leucocytes. An excess of eosinophils is found occasionally in the blood and the serum and was for a time considered distinctive, but no special significance can be attributed to it. In autopsies of bodies of persons dead from pemphigus, only coincidental changes were found, but nothing directly pertaining to the disease.

---

* Read in the Section on Dermatology of the American Medical Association, at the Sixty-first Annual Session, held at St. Louis, June, 1910.

REPORT OF CASE

On March 15, this year, I first saw F. A. S., a farmer, 36 years old. Father died at the age of 60 of pneumonia, mother at 59 of typhoid. Seven brothers and one sister are living and in good health. There is no knowledge of a similar disease in the family. The patient has always been in good health outside of the usual children's diseases. His present trouble began in September, 1909, as small clear vesicles in the mouth, which increased in size and spread to the throat. Two weeks later they appeared in different places over the entire body. At first they remained unbroken and dried up, leaving behind considerable pigmentation which can still be seen. The disease was at that time probably pemphigus vulgaris. Lately the character of the bullæ has changed; they do not last long enough to become filled and tense, are only partially filled and flaccid and rupture rapidly. Large raw patches are produced in this way, partly covered with a sticky serum, partly with shreds of the exfoliated epidermis. The whole body is affected with the exception of the face, especially the lower third of the legs and the buttocks. Between the excoriated areas the skin shows plainly the separation of the horny layer from the subjacent layers by the above-mentioned shriveled finely wrinkled appearance. An exceptional feature, which I find observed only by Weidenfeld[1] was also seen in this patient. A slight rubbing of the skin or a mild trauma, like the taking of a drop of blood from the ear-lobe, was invariably followed by a large bleb. This is probably not so much due to an unstable condition of the vasomotor system of the skin, as in epidermolysis bullosa, as rather to the unstable adhesion of the individual layers of the epidermis. The mucous membranes were affected from the first. The tongue, gums, cheeks and the pharynx are involved presenting sharply outlined raw patches, partly bleeding, partly covered with a loosened grayish membrane. The eruption was at first accompanied by itching which has subsided lately and only general discomfort is complained of. Chewing and swallowing is at times extremely painful and almost impossible. The general health has not suffered much up to the present time, except for an occasional rise of the temperature and an anemic appearance. The patient has, however, lost 70 pounds in his weight since the beginning of his trouble. The urine is acid, specific gravity 1011; no albumin or sugar is present. Blood examination is as follows: Red cells, 4,232,000; white cells, 6,600; hemoglobin, 82 per cent. Differential count: Small mononuclears 40, 20 per cent.; large mononuclears, none; transitional forms 28, 14 per cent.; polymorphonuclears 128, 64 per cent.; eosinophils 4, 2 per cent. As can be seen from this, there is no considerable change from the normal except a decrease of hemoglobin. The percentage of eosinophils is not increased.

400 Bee Building.

ABSTRACT OF DISCUSSION

Dr. M. McMahon, Palmyra, Ill.: I have under observation a case of pemphigus, in an anemic woman, 55 years old, who has worked hard all her life and is broken down in health. The first lesions appeared about six months ago on the buccal mucous membrane, and finally covered the entire buccal mucous membrane, including the gums. After a time, the patient's condition improved to such an extent that she could take food, which she was unable to do at first. Early in March, the first external manifestations of the disease appeared on the face. Other regions of the body then became involved, many blebs forming and breaking down, leaving large areas of denuded skin. Then for a time the patient would improve, only to go through the entire process again with a fresh crop of lesions. Another physician saw the case with me, and confirmed the diagnosis. At the present time, the external manifestations of the disease have somewhat improved, but all the mucous membranes, including the throat, stomach and intestines are now undergoing the same process. The urine, which has been repeatedly examined, contains neither sugar nor albumin, but does contain a large amount of indican. The patient has had all sorts of treatment, arsenic, salicin and quinin being the principal internal remedies, although she had an idiosyncrasy against the latter drug. She appears to be improving at present, but on account of the condition of the mucous membranes, she cannot take a great amount of nourishment. This is the only case that I have seen in the section of Illinois in which I live. I recall a case in the City Hospital about twenty-eight years ago in which the patient was kept in a continuous bath for about six months and finally died.

Dr. H. H. Hazen, Washington, D. C.: I reported a case of pemphigus foliaceus in the *Journal of Cutaneous Diseases*, March, 1910. The patient was a man, 30 years old, who first came under my observation in 1907, and who was referred to me for study by Dr. Thomas C. Gilchrist of the Johns Hopkins Hospital. In going over the metabolism of this case, we found the ammonia output tremendously high. Normally, the ammonia is but 3.5 per cent. to 5 per cent. of the total urinary nitrogen, but in our case the ammonia constituted 15 per cent. of the total urinary nitrogen. This spoke in favor of intestinal infection. The patient was treated with autogenous vaccines in doses ranging from 10,000,000 to 100,000,000. After the first injection he became ill, with marked malaise and headache, pain in the back and limbs, redness and swelling at the site of the inoculation, and an outbreak of a fresh group of vesicles. The reaction was similar to the typical tuberculin reaction. As each injection caused more blisters and malaise, the treatment was stopped. In view of Crowe's work, large doses of hexamethylenamin were given, but without effect. The patient was placed in a continuous bath during the day; at night he slept in bed. After a few days it was noted that the scales had decreased in number, but there was a large number of fresh vesicles which were moist and flaccid. The patient's general condition, however, had improved. He did better under this treatment than any other.

I think that there is need of more thorough investigation of the entire group of pemphigoid eruptions along the lines of modern research. It is not sufficient merely to employ observation. Studies should be made on the following subjects: (1) general metabolism; (2) toxicity of the perspiration; (3) bacteriologic examinations of the blood, bullæ, urine and feces; (4) agglutinating power of the blood.

Dr. E. S. Lain, Oklahoma City: Has any one experimented with the x-ray in these cases? I have had the opportunity of making such a test in two cases during the past twelve months, and under this treatment it has seemed to me that the exacerbations terminate much more rapidly than by any other method that I have tried. In my first case, the lesions ceased to form after the eleventh exposure to the rays. Since then the patient has not been directly under my care, but the lesions have been so few in number that her attending physician did not think it necessary to bring her to the hospital for further treatment. Of course, I do not regard the patient as cured.

In another case, which I saw a month later, the blebs ceased forming after eight exposures to the x-rays. Four weeks later there was a recurrence, but thus far the patient has failed to return to the hospital for further treatment. I have a photograph of this patient which I will show to-morrow at the photographic exhibit.

Dr. A. Schalek, Omaha, Neb.: Dr. Hazen's remark that cases of pemphigus foliaceus have not been studied in a sufficiently thorough manner is not quite justified. The disease is so rare and interesting, especially on account of its serious consequences, that any one who ever had a case generally took the time to study it. In spite of that fact, we do not know much more about the etiology of the disease than we did before. I have watched my cases carefully, and I have had blood examinations and cultures made.

---

[1] Cited by E. Spiegler: Mraczek's Handbuch der Hautkrankheiten, ii, 2.

In my paper, I did not say much about the treatment of pemphigus foliaceus. So far as I know, there is no satisfactory treatment; the patients all die, some sooner, some later. I put my patients in a warm bath for several hours every day, and then have them wrapped in moistened sheets.

EXPERIENCES WITH THE DUODENAL CONTENTS*

MAX EINHORN, M.D.
Professor of Internal Medicine at the New York Post-Graduate Medical School
NEW YORK

The examinations of stomach contents, which were inaugurated forty years ago by Kussmaul and later by Ewald, Leube, Boas, Riegel and others, have now been *generally introduced into the clinical investigation* of digestive disturbances.

The rôle which the stomach and its secretion play in the digestive process has formerly been estimated a great deal higher than at present. At first it was determined that human beings could exist very comfortably without any gastric juice at all (as proved by the numerous cases of achylia gastrica); then it was proven by the surgeons (Schlatter) that the stomach could be excised *in toto* without fatal consequences.

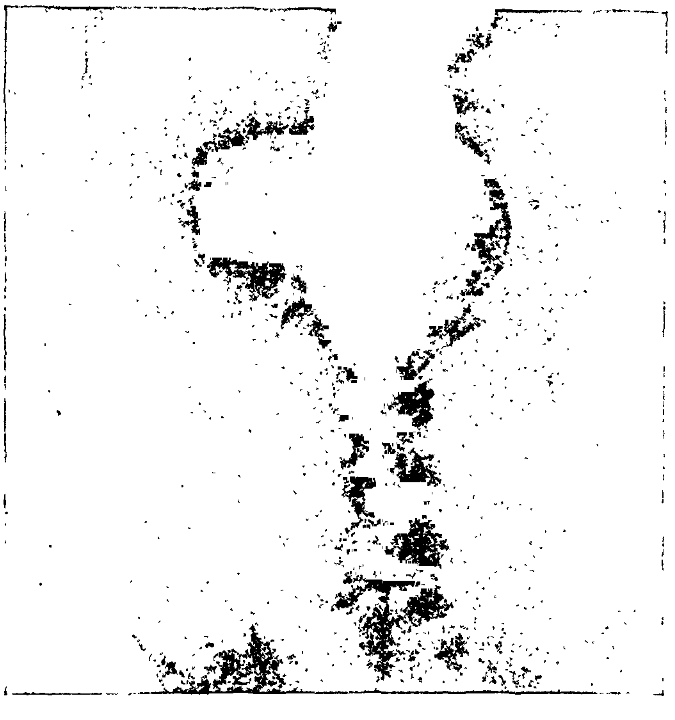


Fig. 1.—Patient T., with the duodenal pump in the small intestine previous to the ingestion of bismuth.

By physiologists as well as by clinicians the principal work of the stomach is now considered to be rather a preparatory process for the real digestion in the small intestine. The principal juices for the latter are contained in the duodenum. The potent pancreatic juice, bile and the duodenal secretion are here poured out. juices have to fulfill two purposes, first, to tritive materials ready for absorption and tralize the strongly acid gastric contents; al wall cannot, as a rule, stand free acids time.

It is, therefore, self-evident that any information as to the condition of the duodenal secretions would be of vast importance. Until recently this was considered hardly possible. Since I introduced the duodenal pump [1] however, the duodenal contents can readily be obtained, and I have therefore, made some investigations on its properties in a number of cases.

The method consisted generally in having patient drink in the fasting condition tea with sugar, without milk and then about half to three-quarters of an hour later introducing the duodenal pump, the patient meanwhile drinking a half tumblerful of water. Later, after one-half to one hour, the patient drinks a glassful of seltzer or hot water or tea and the examination then takes place. Whereas formerly I obtained the duodenal contents through continuous aspiration I now proceed differently, making suction first by means of a syringe and as soon as the contents are obtained removing the piston of the syringe and keeping the barrel of the syringe low. The fluid is thus siphoned out in a slow stream.

I have laid down the results of these examinations in the accompanying table.

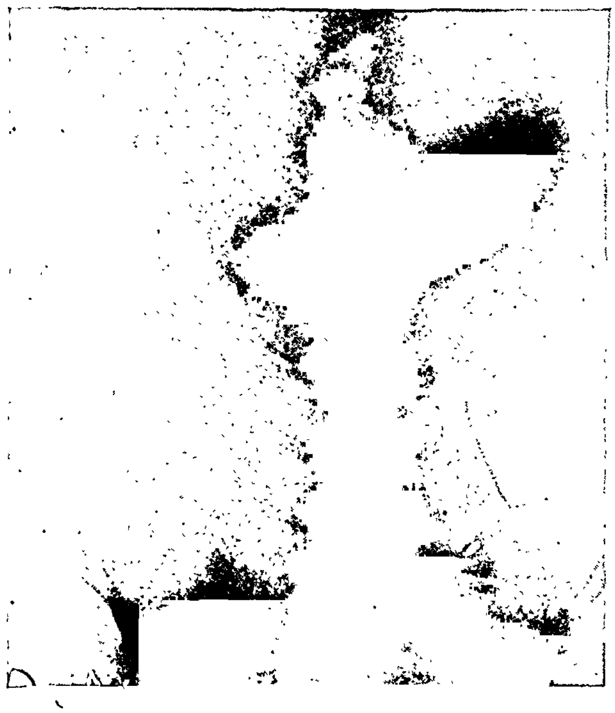

Fig. 2.—Patient T., with the duodenal pump in the small intestine, after the ingestion of bismuth. The contours of the stomach are visible. The tube of the duodenal pump is seen outside of the stomach in the duodenum and small intestine.

COMMENT ON TABLE

If we analyze all the cases of the table we first meet six cases of nervous dyspepsia (1-6) in which trypsin was absent once in the duodenal juice.

In case 8 (chronic gastritis and nervous vomiting) the duodenal contents were thick and turbid, which might point to a duodenal catarrh. In Case 11 (T), with atony of the stomach, steapsin was absent in three examinations and once in examining the duodenal contents in the fasting and dry state (11 E.) all the ferments were found to be absent. In the same patient (11 F.) thick mucus was found once in the duodenal contents after an attack of ptomain poisoning. I append the *x*-ray pictures taken of this patient with the duodenal pump *in situ* (Fig. 1-2).

TABLE OF EXAMINATIONS OF DUODENAL CONTENTS—Continued

No.	Name.	Diagnosis.	Date of Examination.	In What Condition Examination is Made.	Amount in c.c.	Appearance.	Reaction.	Specific Gravity.	Steapsin.	Amylopsin.	Trypsin.	Remarks.
32a.	L.	Chronic Jaundice.	1-19-10	After Breakfast.	..	Yellowish.	Alkaline.	....	+	+	+	Contains bile. Albumin, two-thirds present. Stomach contents show absence of HCl.
32b.	L.	Chronic Jaundice.	3-15-10	After Tea and Sugar.	..	Whitish.	Alkaline.	....	+	+	+	Albumin, one-half present.
33	M. O.	Chronic Jaundice; Tumor of Liver; Hyperchlorhydria	12-16-09	After Tea and Roll	..	Golden Yellow.	HCl. + Slightly Acid.	....	..	..	..	Contents of a golden yellow color mixed with mucus. Stomach contents showed no bile, acidity 90.
34	Bu.	Cirrhosis of Liver.	12-14-09	After Tea and Sugar.	12	Golden Yellow.	Alkaline.	1008	+	+	?	Trypsin very weak. Stomach contents HCl. +
35a.	F.	Cirrhosis of Liver; Euchlorhydria.	2-22-10	After Tea and Sugar.	10	Yellowish.	Alkaline.	1005	+	+	+	Albumin, one-eighth present. Thymus nuclei disappeared. Connective tissue partially dissappeared.
35b.	F.	Cirrhosis of Liver; Euchlorhydria.	3- 1-10	After Tea and Sugar.	10	Yellowish.	Alkaline.	1004	+	+	+	Albumin, one-fourth present.
36	R. H.	Cholecystitis.	12-19-09	After Tea and Roll	..	Yellow, Thick and Turbid.	Alkaline.	....	+	+	O	Stomach contents showed presence of HCI and an acidity of 35.
37	H.	Cancer of Liver.	2-20-10	After Tea and Sugar.	8	Golden Yellow, Mixed with Mucus.	Alkaline.	1004	+	+	+	Thymus nuclei disappeared, connective tissue present.
38	A.	Banti's Disease.	3- 2-10	After Tea and Sugar.	10	Golden Yellow.	Alkaline.	1007	+	+	+	Albumin, remains only in minute trace.
39	Y.	Hyperchlorhydria and Neurasthenia.	3- 6-10	After Test Meal.	8	Golden Yellow.	Alkaline.	....	+	+	Slight	Albumin, two-thirds present.
40	B.	Ulcer of Stomach.	3-14 10	After Tea and Sugar.	10	Golden Yellow.	Alkaline.	1005	+	+	+	Albumin, one-eighth present.

In Case 14 (severe hyperchlorhydria and atonic dilatation of the stomach), in Case 17 (ulcer of the stomach with continuous vomiting), and in Case 33 (hypertrophic cirrhosis of the liver with chronic jaundice and intense hyperchlorhydria) the duodenal contents were acid and contained small quantities of free hydrochloric acid. The tests for the ferments were negative. In all other cases the contents were slightly alkaline or neutral and only rarely slightly acid. Case 15 (hyperchlorhydria and chronic enteritis) yielded a thick mucous fluid, to which later a pure golden yellow bile was added.

Seven cases of achylia of the stomach (19-25) showed twice an entire absence of trypsin and once a weak trypsin reaction whereas the other ferments were present. In one case of diabetes mellitus with normal stomach secretion (27) the contents showed absence of amylopsin, whereas the other ferments were present. Another case of diabetes with achylia (28) showed the presence of all the pancreatic ferments. In Case 29 (cholelithiasis and achylia gastrica) the contents were yellowish and turbid, but contained all the ferments. Four cases of chronic jaundice (30-33) showed the following result: in two (30 and 31) the duodenal contents did not reveal a trace of bile, while all the pancreatic ferments were present. In Case 32 a little bile was present once, another time it was absent. In Case 33 bile was present, mixed with mucus; hydrochloric acid was also present in small quantities.

Two cases of cirrhosis of the liver (without icterus) (34-35) showed good duodenal contents with bile; in one (34) trypsin digestion was very weak. In one case of cholecystitis (36) the contents were yellow but thick and turbid and showed no trypsin reaction.

Case 37 (cancer of liver) furnished a golden yellow juice mixed with mucus, showing all the pancreatic ferments. Case 38 (Banti's disease) showed normal duodenal contents. Case 39 (hyperchlorhydria and neurasthenia) showed weakened trypsin digestion and 40 (ulcer of stomach) normal duodenal contents.

In the column "Remarks" (Cases 7a, 11c and d, 35a, 37) a few experiments have been recorded, to test the relation of duodenal contents in reference to nucleus and connective tissue digestion (thymus and catgut). For comparison the effect of gastric contents on the same substances was noted in each instance. It was found that catgut as well as connective tissue (as contained in the raw thymus gland) can disappear entirely in neutral or weakly alkaline duodenal contents and that the nuclei of the thymus gland can also be digested in the stomach contents. Thus both these specific reactions (connective tissue for gastric digestion, and nuclei for pancreatic digestion) prove themselves to be entirely unreliable and without significance.

Among "remarks" we also find an experiment with secretin, showing the marked influence it has on the augmentation of secretion of bile and pancreatic juice (Case 11f).

I wish to emphasize particularly a few points.

1. *Achylia Gastrica.*—Among the seven cases of achylia gastrica trypsin was absent twice and once was only very weak, whereas steapsin and amylopsin were present. The disturbance of the pancreatic function in the above affection of the stomach explains why we frequently find intestinal troubles associated with it.

2. *Admixture of Mucus.*—An admixture of mucus with the duodenal contents occurs in two ways and is probably of some significance. The mucus may be evenly and intimately mixed with the contents, or it may appear at intervals in the relatively clear contents of the duodenum. The latter would point to the origin of the mucus from the duodenum, whereas its intimate admixture would point to its origin either in the pancreas or the bile passages. Presence of mucus in conjunction with other clinical symptoms (diarrhea, distress some time after meals) would lead us to think of duodenal catarrh (Case 15, Mrs. H. H. R.).

3. *Absence of Bile.*—Occasionally we obtain on aspiration of the duodenal contents at first only a clear or slightly amber-colored fluid. It is of alkaline reaction and contains the pancreatic ferments. Usually after waiting a short time and after repeated aspirations a golden yellow fluid (containing bile) appears. This has no diagnostic significance. If, however, after patient waiting and aspirating, only pancreatic juice but no trace of bile appears, it may be of some importance, particularly in cases of chronic jaundice. If bile is present in the duodenal contents a complete occlusion of the common bile-duct can be excluded. If the bile is entirely missing and pancreatic juice is present, it points to the seat of the obstruction above the common duct.

Even if the results of these examinations are only meager, I should like to call attention to the fact that this field is entirely new and as yet hardly invaded. It might be expected that further work in the same direction will reap rich fruits not only with regard to diagnosis but also for therapy.

20 East Sixty-third Street.

THE CUTTING IN TWO OF A LARGE STEEL PIN WHILE TRANSFIXED IN THE LEFT BRONCHUS AND ITS REMOVAL BY LOWER BRONCHOSCOPY

A BRONCHOSCOPIC PIN-CUTTER AND FRAGMENT-HOLDER, DEVISED TO MEET THE EMERGENCY

W. E. CASSELBERRY, M.D.
Professor-Emeritus of Laryngology and Rhinology in Northwestern University Medical School; Laryngologist to St. Luke's and Wesley Hospitals
CHICAGO

The conditions which result from secondary infection, bound to occur in time at the site of a foreign body, which remains unrecognized or unremedied in the bronchopulmonary tract, must often have been mistaken for primary tuberculosis or other initial disease; for instance, a chronic pulmonary abscess, menacing to life, eluded all efforts to establish its cause until the sudden expulsion by cough of a spicule of bone, which was followed promptly by healing of the abscess. But that secondary infection may be delayed, for weeks or months, with little or no suffering, provided the foreign body be of narrow caliber, non-obstructive and non-absorbent, was notably evident in connection with the glass-headed, 1½-inch, very sharp, black steel pin, which lodged in part at the bottom of the left bronchus and in part within the first bronchial branch of a 15-year-old girl. In this position the pin had remained undisturbed and undisturbing for a period of ten weeks, having caused, during only the first week or two, mild coughing spells with sensations of pin-prick and slightly blood-stained expectoration—symptoms which merely encouraged the family to hope that the pin would be coughed up; while afterward the absence of suffering encouraged the thought that it probably had been coughed up. Freedom from suffering for so long a period naturally leads a patient to forget or at least to doubt the continued presence of a foreign body, and as the physical signs are apt to be equally indefinite it is only since the discovery of the x-ray, supplemented now by bronchoscopic inspection, that a means of positive demonstration has existed.

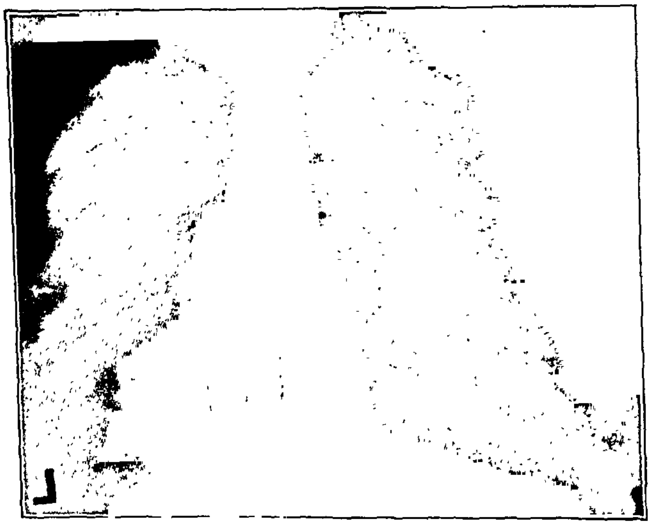

Fig. 1.—Vertical false shadow "very like a pin" on the right side, the real shadow being on the left side, obscured by the sixth rib.

Two delusions, however, in the interpretation of the radiographs, which were taken after physical examinations of the chest at the end of the ten weeks, had failed to elicit any definite signs on which a diagnosis could be based, will serve to remind us of the shortcomings of the x-ray and to accentuate the need, as well as availability, of direct observation through the bronchoscopic tube for orientation of the foreign body in position and for establishing its precise conditions, before one can feel assured of its ready removal. One of these delusions concerned a false shadow on the right side in the first x-ray plate, a shadow "very like a pin," so much so that it was for a time mistaken by every one, whereas the pin was lodged on the left side, its real shadow being visible but obscured in the shade of the sixth rib (Fig. 1). The other delusion resulted from the idea conveyed by the radiograph of a greater than the actual depth of the location of the pin in the bronchi, a fallacy due to difficulty in realizing that the sixth intercostal space at the back, the site of the pin shown in the radiograph, is on a plane not deeper than that of the third rib in front (Fig. 2), and that the bottom of the bronchus at the site of its first branch, where the pin was found, corresponds to the same plane. Notwithstanding comparative measurements, I was expecting to meet the pin lower down in the bronchial tract.

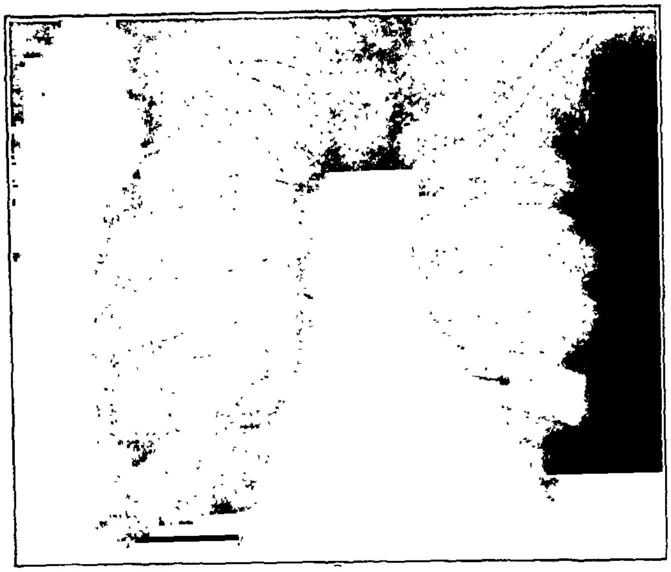

Fig. 2.—The pin in the left sixth intercostal space at the back, on the same plane as the third rib in front, and at the same level as the first bronchial branch, where the pin was found.

The manner in which the accident occurred is worthy of comment in order that women may be warned against a certain habit while dressing, for the pin had dropped so easily and naturally into the bronchial tubes, lodging where its transfixion by the impact of cough was inevitable, that one must regard it as an accident liable to repetition.

The young woman, with pin in mouth and skirt in hand, in readiness to drop the skirt by encircling it over her head, raised very high her outstretched arms—an act which is identical with the first movement in Sylvester's method of resuscitating suffocated persons, a method which owes its power to the fact that raising the arms, forcibly expands the lungs and causes an inrush of air, the mouth opening, itself, as if by instinct; and, at the same moment, in readiness to let the skirt fall clear of her hair, the head was thrown backward and face upward—an attitude which is identical with the sword-swallower's position, so called because it brings the mouth, larynx and windpipe into a straight vertical line. The pin, let loose by the involuntary parting of the lips, simply dropped, with the air-current, head foremost straightway into the left main bronchus, and on downward till its head and two-thirds of its stem had passed into the first bronchial branch, where that much of it became hidden from bronchoscopic view in the upturn by which this branch is given off to supply the upper lobe. The pin, being too long to make the turn completely, was arrested, evidently, with its head compressed against an upturning segment of the bronchial branch. The point, carrying one-third portion of the stem, which alone remained exposed to bronchoscopic view, projected from the orifice of the branch diagonally upward across the rear segment of the main bronchus, its end impinging against and its point inserted into the wall of the bronchus (Fig. 3).

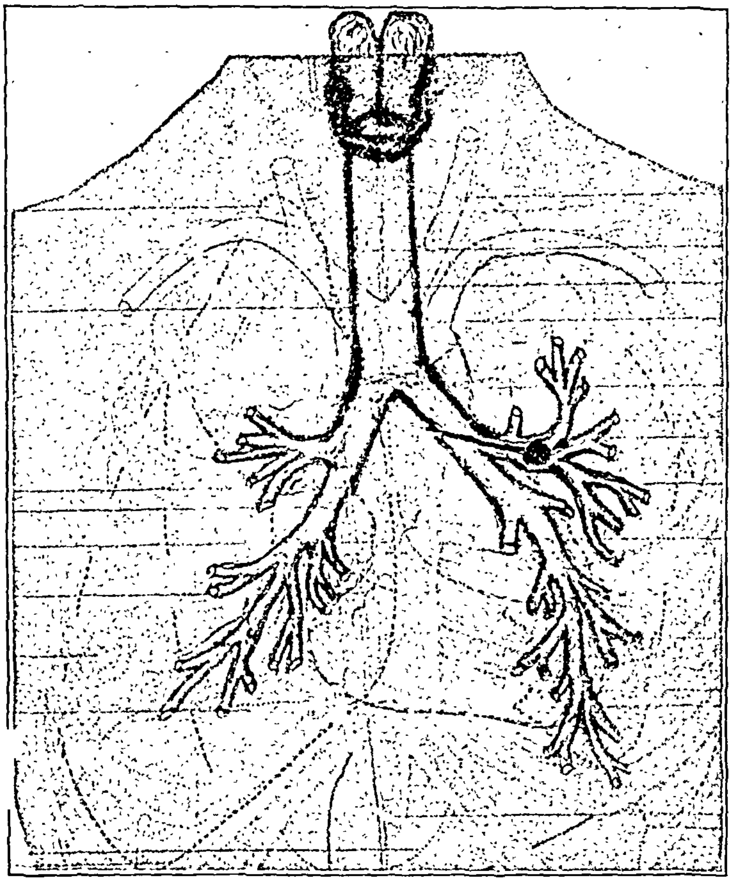

Fig. 3.—The transfixed position of the pin in the bronchial tree (Jackson) and thorax (McClellan).

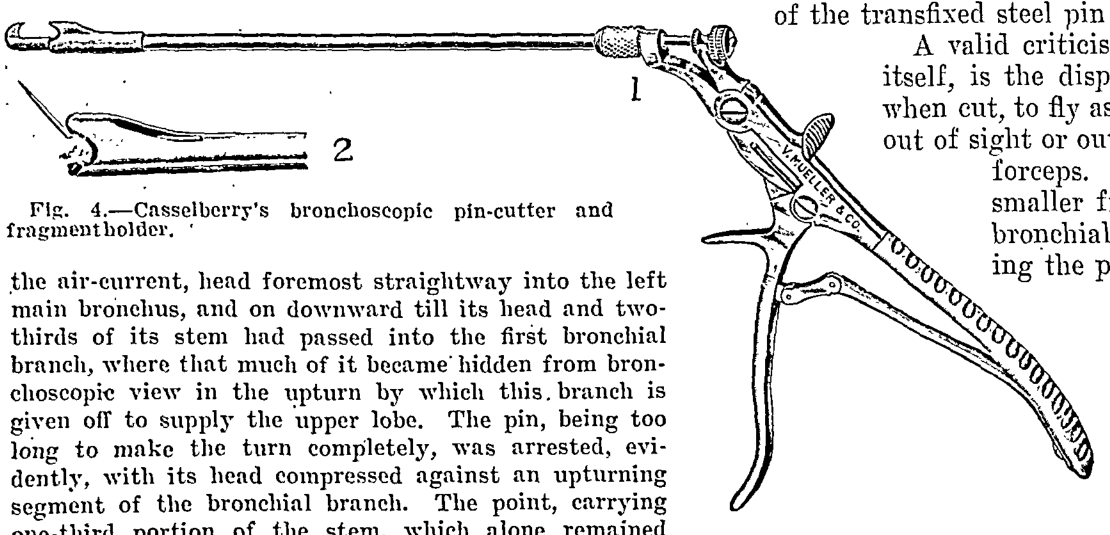

Fig. 4.—Casselberry's bronchoscopic pin-cutter and fragmentholder.

The precise location of the pin, with the fact of its transfixion, was first ascertained only by the upper bronchoscopy at the first operation, an operation which, though it failed for the moment to remove the foreign body, fulfilled its avowed alternative purpose, to obtain information which would enable one to remove the pin at a subsequent operation, and without which the plan of cutting the pin in two could not have been formulated. The fact that both ends of the pin were up against a barrier explains how, by the impact of cough, the pin-point had been driven so firmly into the bronchial wall and why the repeated efforts at the first operation to displace the pin should have failed.

I need not particularize the first operation except in so far as these efforts to displace the pin tended to show the actual necessity for cutting it. A skilled first aid, Dr. G. P. Marquis, an expert anesthetist, Dr. Herman Peterson, an excellent mechanician, Mr. V. Mueller, suitable hospital facilities at St. Luke's and approved appliances were all at hand, the patient's head being satisfactorily held in the Boyce position by Dr. E. W. Bodman. Tubes of the Brunig-Killian and Jackson types were passed by the mouth through the larynx and downward, the first one, inadvertently, being passed over and beyond the pin, which rather hugged the back wall of the bronchus, but on withdrawing the tube somewhat, the exposed third of the pin came plainly into view. No difficulty was encountered in grasping the pin repeatedly through the tube, at a depth of about 11 inches, with various bronchoscopic forceps, the grasp being renewed to change forceps or the vantage-point of its grip no less than twenty times in order to apply leverage and reasonable force in every promising direction; but all without avail, other than a spontaneously uttered conviction, when the attempt was given up for the time, that the pin must first be cut in two.

Among the multiplying number of foreign bodies in the bronchial tract which are now being brought to light through the efficiency of the bronchoscopic methods introduced by Killian and advanced by Jackson, Ingals, Coolidge, Mosher and others, it is probable that additional cases complicated by transfixion will be encountered; hence, I propose as a general principle, the plan adopted in this case, of facilitating the bronchoscopic extraction of immovably transfixed pointed objects, such as pins, needles and perhaps open safety-pins, by first dividing them, via the bronchoscopic tube, into two or more parts; and I commend the instrument or pin-cutter devised for this purpose as a desirable addition to our bronchoscopic apparatus. The chief import of my theme can be expressed in the statement that, had the device (Fig. 4) and the principle now proposed for its use been already in vogue, a second operation for the extraction of the transfixed steel pin would not have been required.

A valid criticism, which will at once suggest itself, is the disposition of the parts of a pin, when cut, to fly asunder, hence, possibly, to drop out of sight or out of reach of the bronchoscopic forceps. Thus, I feared that my smaller fragment might get lost in the bronchial secretion and, as after dividing the pin, less than a quarter-inch of the larger fragment would remain exposed, I feared that it might disappear, by retraction, wholly around the curve of the bronchial branch. But neither of these contingencies occurred. I had modeled in the rough the beak-shaped slotted scissor-like device shown in Figure 4, to cut into two pieces, not punch into three, with the expectation, further, that one of the two pieces might adhere in its beak, thus limiting at least the scattering of fragments. My suggestions were skilfully elaborated by the makers (V. Mueller & Co.), and happily the mechanism even exceeded my expectations in this regard. I observed while testing the instrument that not only, as expected, would one of the fragments adhere in the serrated slit alongside the bevel, but that it adhered with dependable regularity and firmness as long as the blades were not permitted to reopen; moreover, as it was invariably the end of the pin next to the beveled side of the blade which so adhered, the operator could elect the fragment to be held and the one to be let loose, provided the pin were transfixed in space enough to admit the jaws either under or over it, hence to turn the blade bevel next to whichever end he might elect.

Profiting by these test observations, I planned to minimize the risk of losing my smaller fragment by electing it to be held in the grasp of the pin-cutter, and to diminish the risk of letting loose my larger fragment by cutting it off not too close to the bronchial branch. Beyond these precautions the chance that the fragments might still get lost was, I felt, a bare chance that must be taken.

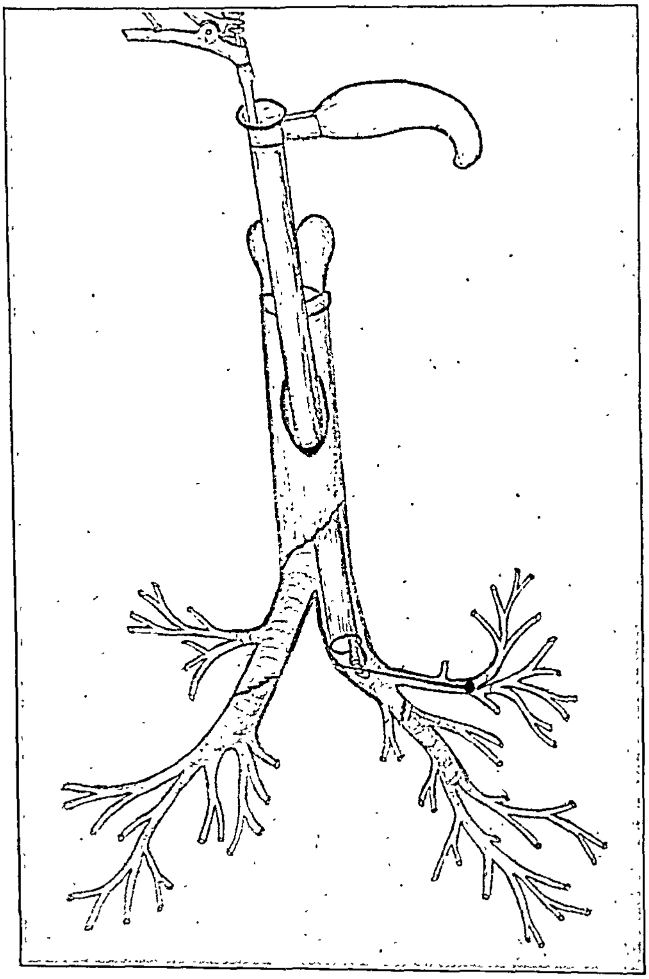

Fig. 5.—Diagram showing the method of cutting the transfixed pin in two.

I questioned the absolute necessity for shortening the route to the pin by opening the windpipe, but considering the novelty of the procedure of cutting the pin *in situ*, a position none too near at best, I deemed it inexpedient to add uncertainty by adding distance. It is now realized, however, that the pin-cutter and the principle of its use are applicable as well at the longer range of upper bronchoscopy. In fact, the only uncertainty encountered in the final operation was, not in cutting the pin, but in finding it before cutting it, a delay which was incidental to the tracheal opening, for the bronchoscopic tube, when entered at the incision was deflected by the chin somewhat out of its most favorable line; so despite the distally lighted Jackson tube, augmented by a Brunig-Killian headlight, and the best conditions for artificial lighting in the semi-darkened throat-room of St. Luke's Hospital, a combination which yielded a brilliant illumination of the bronchial tree, the pin, for a time, could not be seen. The same competent aids were present but having made the low tracheotomy as a first step in this operation, the patient's head had not been adjusted precisely in the Boyce position. A readjustment of the head caused the chin to drop out of the way, when on passing the tube again through the tracheal opening but directing it as nearly in the median line as during the upper bronchoscopy at the first operation, the pin came plainly into view, being in the same location and in the same state of transfixion. A few aditional efforts to extract it without cutting having proved futile, the pin-cutter (Fig. 5) came next in order. It operated exactly as planned; one could hear the snap, see the larger fragment shiver and then discern the small pointed piece in the beak of the instrument, held fast in which it was withdrawn. The larger piece settled somewhat, but its short exposed end was now an easy mark and in another minute, in the grip of a Jackson forceps, it also came safely out. (Fig. 6.)

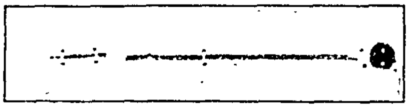

Fig. 6.—The pin in two parts; actual size.

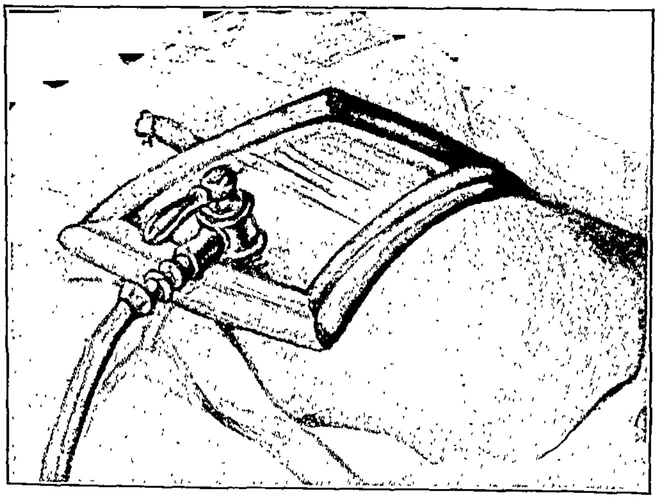
A PNEUMATIC SHIELD FOR OPERATIONS ON THE LUNG

W. WAYNE BABCOCK, M.D.
PHILADELPHIA

In thoracic surgery in man, positive or negative pressure devices are rarely essential. Either pleural cavity or even the anterior mediastinum may be invaded without, as a rule, a fatality from operation pneumothorax. It is a source of satisfaction, however, to have available an apparatus capable of almost instantly removing the condition of pneumothorax.



A pneumatic shield for operations on the lung.

In 1908[1] I devised an aspirating shield to be applied over the wound under such conditions. The present shield is modified by omitting the metal rim and glass window which interfered with accurate coaptation to the chest wall and substituting a simple inflated rubber rim in which is held a flexible celluloid window. The apparatus may be sterilized in the autoclave or in boiling water. A simple two-way cock connects the cavity of the shield at will with either the external air or a suitable vacuum tank. To overcome pneumothorax the shield is applied over the wound and the lever turned connecting the vacuum tank with the cavity of the shield until the lung is sufficiently inflated. The partial vacuum may be continued, or, if desired by gradually turning the lever so as to admit air one may observe the effect of a gradual reproduction of the pneumothorax. A form of artificial respiration may be produced by alternately producing and relieving the negative pressure in the thoracic cavity. The instrument may be applied during the suturing of the wound by moving the shield just in advance of the introduction of sutures. A final aspiration with the aspirating tube to free the chest of any residual air may be employed as the last suture is tightened. The large transverse area of the tubing renders the instrument efficient despite imperfect coaptation and considerable leakage. Leakage may be reduced by applying wet gauze against the sides of the shield. A regulating valve connected with the vacuum tank is desirable to prevent too violent aspiration and the production of traumatic emphysema.

THE CLINICAL RECOGNITION OF THE SCAPHOID TYPE OF SCAPULA AND OF SOME OF ITS CORRELATIONS*

WILLIAM W. GRAVES, M.D.
Assistant Professor of Neurology in the St. Louis University School of Medicine
ST. LOUIS

In my communication, "The Scaphoid Scapula, a Frequent Anomaly in Development of Hereditary, Clinical and Anatomic Significance,"[1] presented to the St. Louis Medical Society, Feb. 5, 1910, I indicated the relative frequence of the scaphoid type of scapula in our population in dry bones and in fetal, embryo and monster forms. The main thesis of that communication was: The scaphoid scapula is an anomaly in development originating in the progeny from some abnormal circumstance operating in the parents, is thereafter transmitted from parent to child, and so on through several generations, and unless the abnormal circumstance again becomes operative in the descendants, the scaphoid scapula finally disappears and the racial type again becomes dominant.

I showed that it occurred most frequently in individuals deviating from the average in physical or mental endowments, or both, and stated that the natural habitat of the scaphoid scapula was in the deviate. I showed further that in individuals of the second generation in whose parents a definite abnormal circumstance—syphilis—had operated, the scaphoid type of scapula was correlated with certain conditions, such as nocturnal incontinence; with certain physical signs, such as catarrhal affections, adenoids, an abnormal degree of lymph-gland palpability, and above all, with vasculosclerotic changes occurring very early in life; in some detectable by the ordinary methods of clinical investigation as early as the fourth, and as a rule as early as the tenth, year of life; and in older individuals a degree of arteriosclerosis out of all proportion to their years. Even in individuals of the third and fourth generations, the last-mentioned correlations, amounting almost to parallelisms, will be frequently found. It is to the clinical recognition of the scaphoid type of scapula and of the correlations just mentioned, and to the recognition of others in the living subject, that I desire at this time to direct attention, since the appreciation of certain of these correlations is fundamental in the study of the causation of the scaphoid type of scapula and in the consideration of the many weighty and intricate problems that appear to be intimately associated with it.

The recognition of the scaphoid type of scapula in the living subject will not be found difficult if one remembers its characteristics as shown by my studies of dry bones, embryonal and fetal forms. Of these characteristics the following are usually readily discernible in the living subject: first, the vertebral border below the scapular spine is more or less concave; this may be almost or quite straight, slightly or distinctly concave; second, the scapular index is as a rule less; that is, the bone is longer in proportion to its breadth than in the average type (this may be roughly estimated in the living subject by noting the proportion between length and width of the body of the bone); third, the vertebral border in the scaphoid type more nearly parallels the

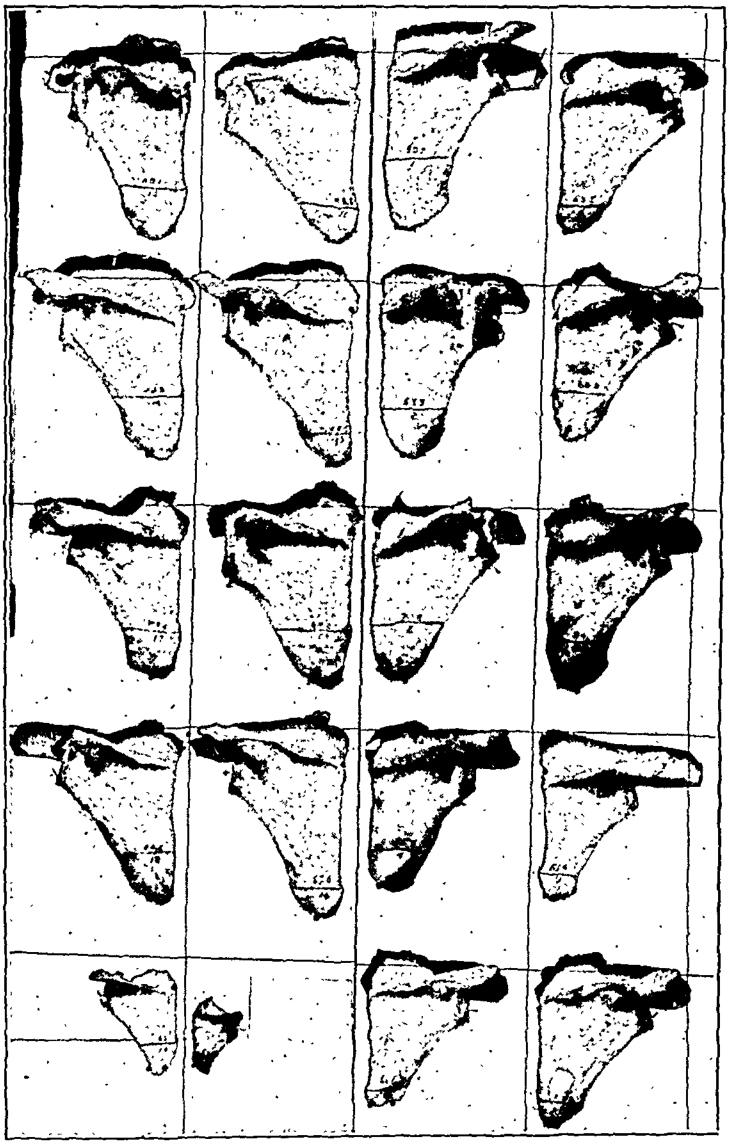

Fig. 1.—A group of scapulæ of the scaphoid type, all having rather decided incurvations of their vertebral borders.

---

* Presented to the St. Louis Medical Society, May 14, 1910.

[1] Med. Rec., May 21, 1910, p. 861.

long scapular axis and a straight line than in the average type of scapula; fourth, as a rule, the spine in the scaphoid type forms more nearly a right angle with the long scapular axis than does the spine of the average type; fifth, the vertebral border buds, tuberosities, varying in size and number, are much more common in the scaphoid, especially in those nearer straight, than in the average type of scapula; sixth, in the same subject having scapulæ of the scaphoid type, differences in size and form and specific differences in the contour of the vertebral borders are common.

Only in exceptionally thin individuals may one determine the other characteristic of the scaphoid type of scapula previously described; namely, the constant absence of lips and intermediary surface in those scapulæ which have marked concavity of the vertebral borders. Two or more characteristics will invariably be found in those individuals having the scaphoid type of scapula and these may usually be determined by inspection and palpation. In individuals who are exceptionally muscular or obese, the *x*-ray may supplement inspection and palpation, an expedient I have not thus far found necessary.

As a matter of course all clothing must be removed, at least to the hips, and the patient should assume his natural attitude, standing several feet in front of the examiner in good illumination. To appreciate natural attitudes fully, the patient should be inspected from the front, laterally, and from the rear, during which the shape of the chest, the abdomen, the course of the clavicles, the length of the neck, the muscular development, the spinal curves, etc., are studied. Then by examination of the scapular region, in average individuals the upward and outward slant of the scapular spines, the graceful downward and outward curves of the vertebral borders beneath the fibres of the trapezii and the underlying mass of the rhomboids attached to these borders may be made out easily. The course of the long scapular axis may thus be readily determined to be downward and outward, so that the bases of the scapular spines will be found to be from 2 to 6 cm. nearer the spinal axis than are the inferior angles.

In individuals having the scaphoid type of scapula, the picture is completely changed. The chest is frequently narrowed in all diameters, especially anteroposteriorly. There is often a narrow costosternal angle and floating tenth ribs; the clavicles very frequently take rather a horizontal course increasing the dimensions of the supra-clavicular regions, and there is often undue prominence of the acromioclavicular articulation. The shoulders hang, drooping downward and forward. The vertebral borders stand out prominently, wing-like, and especially that portion of the borders merging into the inferior angles. There is paralleling of these borders with each other and of these with the spinal axis, so that the distance between the inferior angles of the scapulæ and the bases of their spines is nearer equal, and in some instances the bases of the spines are further away from the spinal axis than the inferior angles of the bones. In many instances, even when the individual is caused to approximate the vertebral borders of his scapulæ by drawing the shoulders directly backward, the phenomena just described will still be apparent, though to a somewhat less degree. The sluggish attitudes of such individuals, especially of the shoulder regions, the frequent lowering of one shoulder and usually on that side where the scaphoid type of scapula is most marked, the changed relations of the vertebral borders with each other and of these with the spinal axis, have their foundation in the anatomic characteristics of this type of scapula mentioned above.

In individuals having average scapulæ, marked differences between them in the same individual will rarely be found; but this is so frequent in the scaphoid type of the scapula that it must be considered as one of its chief characteristics. Marked differences will be noticed not only in the contour of the vertebral borders, but in some cases in the breadth and length as well. The differences in size, and especially the differences in contour of the vertebral borders, should also be considered in determining the presence of the scaphoid type of scapula. In the cases in which the difference is quite decided, causing the lowering of the shoulder on the side where the scaphoid type is most marked, lateral curvature of the spine is not infrequent. In some individuals who have acquired better attitudes of their shoulder regions an accentuation of the anterior curve in the dorsolumbar region occurs.

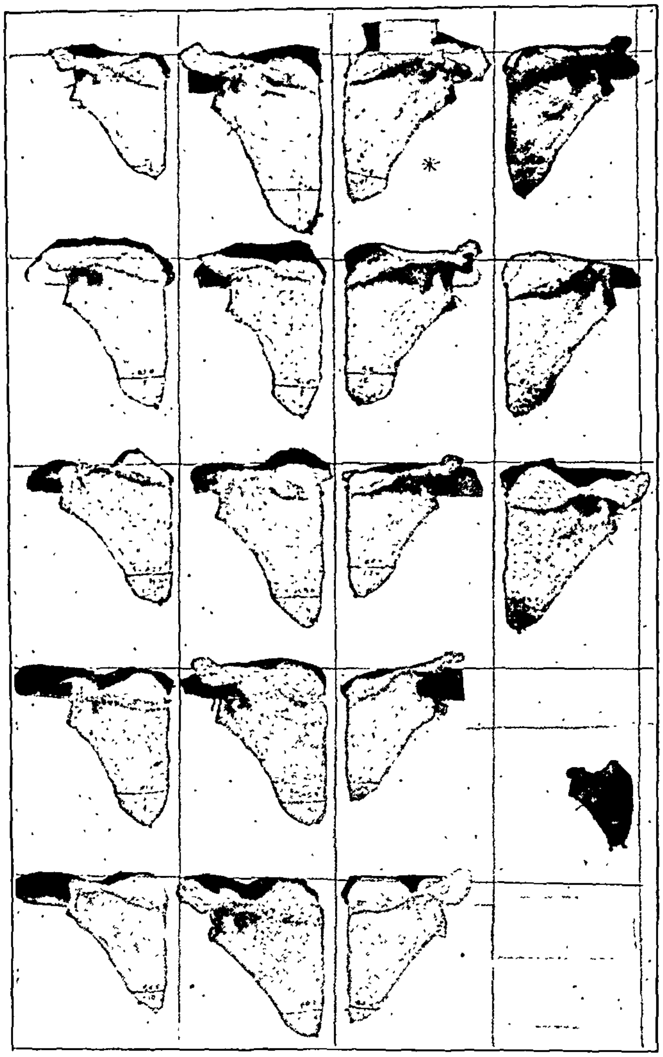

Fig. 2.—A group of scapulæ of the scaphoid type, all having more or less straight vertebral borders except the one with a star next it, whose border is slightly convex—a border-line scapula.

In thin individuals having the scaphoid type of scapula, the hollowing out of the vertebral borders may be readily appreciated merely by inspection. But to appreciate this better and the degree of it in each scapula, to appreciate the shapes of the bones as well as the presence of the vertebral border buds, palpation of the scapula should not be neglected. The marked differences of shape and size of the scapula, as well as the degree of concavity of their vertebral borders and the number and size of the vertebral border buds, may be well appreciated in the living subject; but to facilitate this study, I reproduce here three series of bones illustrating the anatomic characteristics found in my studies of dry bones (Figs. 1, 2 and 3).

Before considering the clinical recognition of some of the correlations of the scaphoid type of scapula and the better to appreciate these, it will be well for the moment to direct our attention to the individuals in whom these are associated, and then by looking at a composite picture of such individuals to study the correlations at closer range. Confining our studies in the beginning to the individuals in whose parents an abnormal circumstance—syphilis—has operated, we shall find that such individuals, as previously pointed out, are of retrograding, deviating types. In any one of these, when compared with either parent or with his cousins, his uncles and aunts or with the average members of the community in whose parents the abnormal circumstance has not operated, deviation will be found in the physical or mental development, and usually in both. Among such progeny will be found many of the heretofore recognized anatomic, physiologic, psychic and psychoneurotic stigmata which I shall not here particularize.

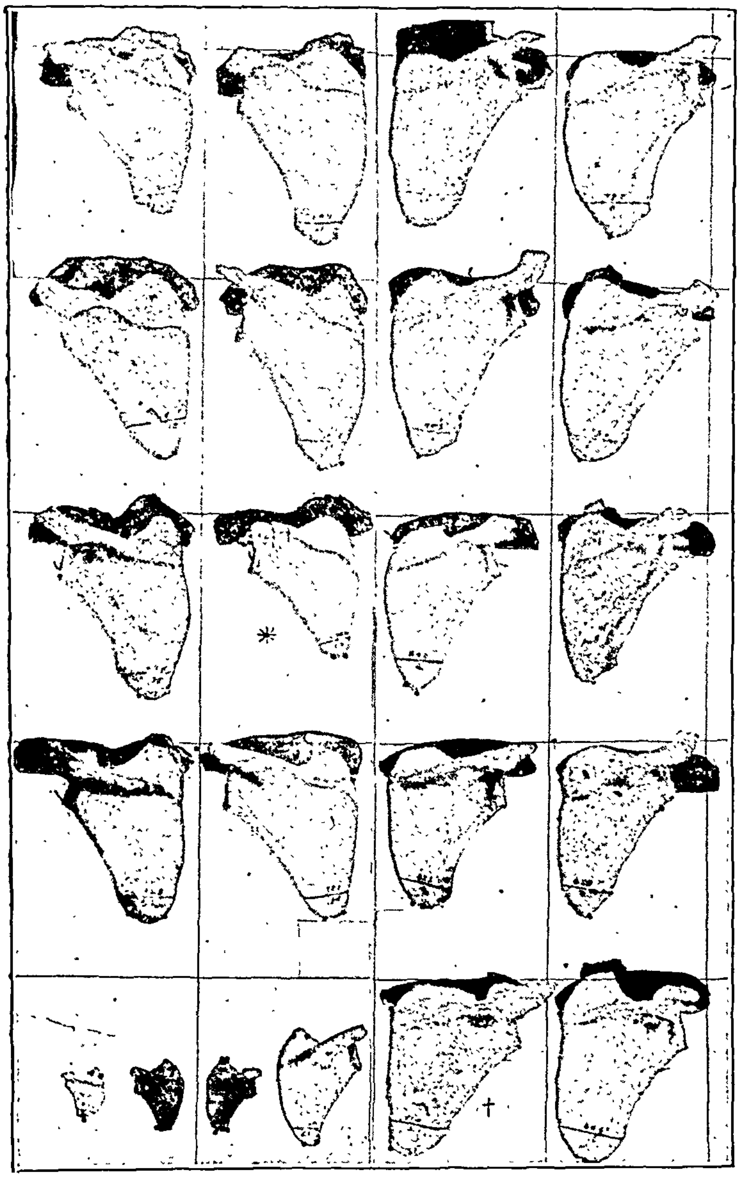

Fig. 3.—A group of average scapulæ, the dominant racial type, excepting the one with a star and that with a dagger near, these being border-line scapulæ but nearing the average type.

In only a few instances have I thus far found the well-marked scaphoid type of scapula in individuals even approaching average development. Such individuals are usually undersized, have sluggish attitudes, meager musculature and are strikingly lacking in the harmonies of physical development. They range in stature from dwarfs to giants, but whether the one or the other, or merely undersized, disharmony characterizes their physical development. Many of them, apparently physically normal at birth, in their later development show retardation or grow by fits and starts until near, either before or after, the usual age of puberty, they shoot up like weeds or forever remain stunted—blighted.

With the beginning of mental development such progeny are either backward and remain so, or they show—and this is the rule—precocity. If disharmony characterizes their physical development, it is especially true of their mental development. They have no childhood. They seem almost to jump from the cradle to adolescence. "My children are old in their ways" is a frequent expression of certain observing mothers, and they may add "They are almost always ailing." Or the unobserving mothers (and ignorance and mother-love and pride makes them so) may proudly say "My children are all healthy." Indeed, physicians usually consider such children healthy, or at least free from syphilitic blight, in the absence of "snuffles," eruptions of the skin and mucous surfaces, bone and joint affections, Hutchinson's teeth, interstitial keratitis, and deafness without otitis. Children of the second generation are as a rule older than their years; they are often ailing and are rarely healthy; but to appreciate the truth of these assertions we must, as physicians, study the individuals of families rather than the histories of individuals of families.

While idiocy, imbecility and backwardness in mental development are relatively frequent in the second generation, such mental states are by no means common. My studies of the offspring in whom an abnormal circumstance—syphilis—in the parents is beyond question, show precocious mental development to be the rule. Not only do such children appear like little old men and women in the seriousness of their ways and actions, their preference for books rather than play, and the society of their seniors rather than their kind; but as individuals, their facial expression is lacking in the freshness of infancy, childhood or youth and they ever afterward appear much older than their years.

Many of them develop sexual instincts long before puberty, and these are often gratified by masturbation, sexual intercourse, or otherwise. Strenuosity and intensity characterize many of these individuals, and before or during adolescence such mental proclivities, associated with the inherently weak constitution, sooner or later lead to an inevitable "break," and they make up a large percentage of the cases commonly classified as neurasthenia, hysteria and dementia præcox. Many cases of epilepsy developing in early or later periods of life are to be found in the individuals of the second and later generations. The incorrigible and so-called criminal classes are increased from the ranks of the second and later generations in a degree probably unequaled by that of any other source. Not a few individuals of the second generation, and many of the later generations, despite their handicap in physical and mental endowments, by learning to adjust themselves to their environment, lead successful, useful and even brilliant lives, though they rarely live out their expectancy in consequence of their abiotic natures.

If the antenatal mortality of syphilitic progeny is so great, it is but reasonable to believe that the influences underlying it are still operative in the living; if not the disease itself, its blighting influences as manifested by disharmony in physical or mental development, or both, by inability to stand the stress and strain of ordinary existence, by degenerative and involutional changes, and by lowered general resistance. Such progeny are truly abiotic; hence the instability of their natures, their proneness to so-called functional disturbances and to disease, to degenerative and involutional changes, to neuroses, psychoneuroses, psychoses, and above all, to tuberculosis.

In my studies of the scaphoid type of scapula and its correlations[2] I have been greatly impressed by the unusual frequency of tuberculosis in such progeny and in the progeny of later generations. This is not the place to dwell on the ramifications of the scaphoid type of scapula and some of its correlations in general and special pathology, but it seems proper to mention here the abiotrophies of Gowers, the neuroses and psychoneuroses and especially epilepsy, dementia praecox and tuberculosis, since my studies have shown the unusually frequent association with these conditions.

Nocturnal incontinence is relatively frequent in individuals having the scaphoid type of scapula and other correlations. It was present in about 16 per cent. of fifty boys, inmates of St. Joseph's Orphan Asylum, studied in a preliminary way, and it is such a very common condition in the second generation that it may well be considered one of the correlations of the scaphoid type of scapula. Fuchs[3] and Mattauschek,[4] in studying enuresis nocturna in adults, have shown in their cases anomalies of skin and tendon reflexes, slight sensory changes about the feet, syndactylism, deformity of the feet (pes planus, varus and valgus, etc.), the frequent association of the patency of the sacral canal in all degrees from spina bifida to the slightest change in the form and location of the sacral hiatus, the latter demonstrable only by the *x*-ray.

These findings caused Fuchs to assume an actual defect of development (myelodysplasia), meaning thereby an anomalous development about the lower part of the spinal cord. Fuchs has correlated the assumed myelodysplasia with distinct anatomic anomalies, and I have correlated similar anomalies with the scaphoid type of scapula.

The histories of catarrhal affections, tonsillitis, bronchitis, gastro-intestinal disturbance and adenoids, are unusually frequent in individuals of the second and later generations.

Of the boys studied in St. Joseph's Orphan Asylum having the scaphoid type of scapula and some of its correlations, about 60 per cent. are mouth-breathers. In a family of five children of the second generation, recently referred to Dr. R. P. Scholz, adenoids were found in all, and in four to a degree requiring operation. In a group of ten backward public school children studied with Dr. Scholz, having adenoids and mentioned in my first communication, all had the scaphoid type of scapula and other correlations. Since then Dr. Scholz has kept a careful record of those operated on by himself for adenoids, and in a recent conversation he informed me that fully 75 per cent. of them have the scaphoid type of scapula and some of its correlations. Adenoids, therefore, appear to be a very frequent correlation of the scaphoid type of scapula. The "adenoid face," consisting in a dull, vacant expression, dry and separated lips, poorly developed nostrils, etc., discerned by visual or digital examination, or both, renders the recognition of adenoids an easy matter.

A more frequent correlation is undue lymph-gland palpability, and this is so frequent that it is well-nigh constant. Enlarged anterior cervical glands are an almost constant accompaniment of adenoids, but the postcervicals, epitrochlears, and those above and below Poupart's ligament are those more easily palpable and those less frequently involved from peripheral infections; but even these enlarged from peripheral infections, the postcervicals from infections of the posterior portion of the scalp, the epitrochlears from infections of the more distal parts, and the inguinals above Poupart's ligament from infections about the genitalia and below, of the distal parts of the extremities. In any case, the history or the presence of such infection, and above all the equal enlargement, right and left, will usually enable one to determine whether or not the enlargement is peculiar to the individual or due to some peripheral infection.

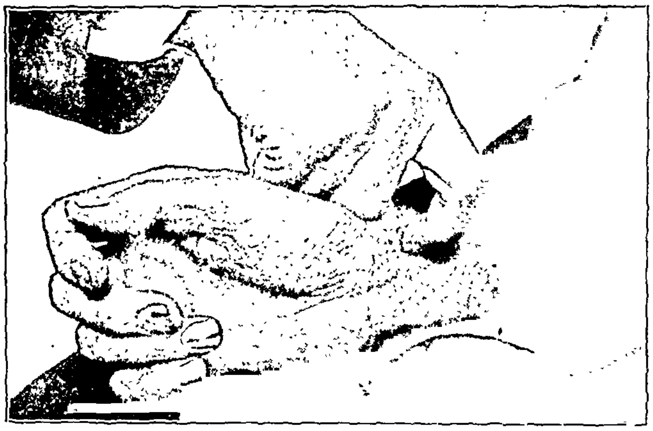

Fig. 4.—A method of finger-tip palpation of the radial artery.

Pupillary anomalies, consisting of asymmetries and differences in size, are so common in individuals of the second generation as to rank as frequent correlations. Such findings should be considered only when neither iritis nor iridocyclitis causing synechia has existed, points readily determined by the history and inspection. In searching for pupillary anomalies, it must be remembered that clumpy distribution of pigment along the pupillary margin ("Ektropium des Pigment-Blattes der Iris"—Bach[5]) may cause a perfectly symmetrical pupil to appear flattened, oblong or cornered. The examination by focal light may readily exclude this condition. The Argyll-Robertson pupil with an otherwise intact nervous system is relatively infrequent in the second generation, though almost invariably associated with the scaphoid type of scapula and other correlations when present. The same may be said of Hutchinson's teeth, interstitial keratitis, deafness without otitis, hypotonia of certain muscle groups, absent knee-jerks and the usual signs of congenital lues heretofore recognized. Juvenile paresis and tabes are almost invariably associated with the scaphoid type of scapula and its chief correlations, and in my first communication I pointed out the frequency of this association with syphilis of the nervous system, with acquired tabes, paresis and other abiotrophies of Gowers.

---

[2] In a paper soon to appear, prepared in collaboration by Dr. O. H. Brown and myself, we shall show the frequent association of tuberculosis with the scaphoid type of scapula and some of its correlations.

In my studies of senility, of the later manifestations of acquired lues, and of individuals having the scaphoid type of scapula, I have been impressed with the peculiar appearance of the conjunctivæ over the sclerotics, which I have noted in my findings as "varnished scleræ." The varnished sclera is present as a rule in healthy individuals as early as the thirty-fifth or fortieth year of life and it increases with succeeding years. Its chief characteristic is a shiny, glistening appearance on a rather undulating, and in older individuals, a slightly yellowish background, so that the surface of the conjunctiva lying on the whitish sclerotic glistens like the cornea. In individuals free from senile changes the surface of the conjunctiva has a more smooth and less shiny appearance—is even dull when compared with the surface of the cornea; so that in such persons there is a distinct contrast between the brilliancy of the surface of the cornea and that of the conjunctiva on the bluish-white background of the sclera. The lack of contrast, on the other hand, is probably one reason for the expressionless eyes of tabetics and paretics and the main reason for the "settled look" in the healthiest of us after the thirty-fifth year of life. The undulating appearance is probably due to wasting of the episcleral or subconjunctival tissue and to the thickening of the walls of the conjunctival vessels, and, in addition, in older individuals, to wasting of the conjunctivæ analogous to that of other mucous surfaces and the skin in senility. The presence or absence of "varnished scleræ" may be readily determined on drawing down the lower lids when the patient is facing the light and directing his gaze somewhat upward. In such position we may readily appreciate the appearance of the conjunctiva if varnished, its tints, its undulations, and lastly, the undue tortuosity of the conjunctival vessels—a sign usually associated with and paralleling it. When the "varnished" appearance is well marked the tortuous vessels seem to lie, rather, on than within the conjunctival tissue. Punctate hemorrhages into the conjunctival and even into episcleral tissues will frequently be found associated with the signs just mentioned.

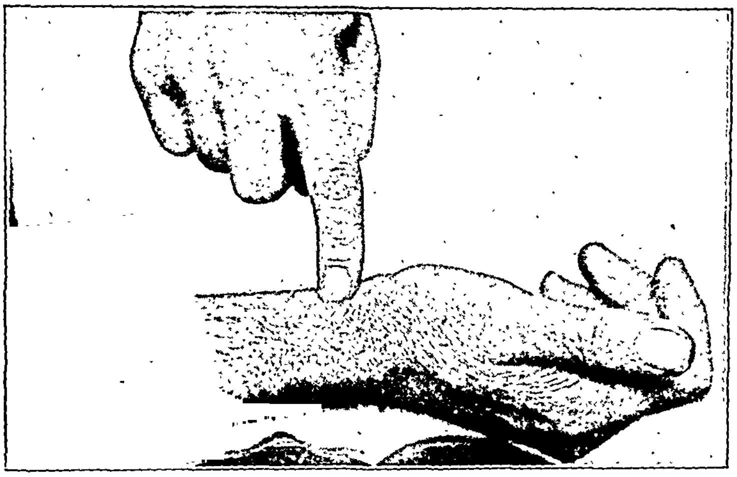

Fig. 5.—Another method of finger-tip palpation of the radial artery.

Aside from the chief correlation of the scaphoid type of scapula, namely, the characteristics of the whole individual, probably the most constant, and to my mind the next in importance, is the correlation of vasculosclerotic changes at an unusual period of life and in older persons out of all proportion to their years. The varnished scleræ and the undue tortuosity of conjunctival vessels are probably due mainly to vasculorsclerotic changes of the conjunctival vessels. The study of these vessels with Luedde's modification of the Zapski binocular corneal microscope, as previously pointed out, appears to offer a ready means of detecting the presence of vasculosclerotic changes, from whatever cause, long before they might otherwise be recognized in the living subject. At any rate this instrument offers additional means of securing corroborative evidence—and it is impossible to have too much of this. With this instrument one may readily see the blood coursing through the conjunctival vessels and discern thickening, crinkling and aneurismal dilatations of their walls.

In certain congenital deformities correlated with the scaphoid type of scapula, studied conjointly by Drs. Luedde and V. P. Blair, evidence of such changes have been found in the conjunctival vessels of nursing infants. By the ordinary methods of clinical investigation, as previously pointed out, I have found evidence of vasculosclerotic changes as early as the fourth, and almost constantly as early as the tenth year of life in individuals of the second generation. A number of these, studied by me, have also been studied by Dr. Luedde and in no instance has he failed by studying the conjunctival vessels to find evidence of vascular changes. The almost constancy of vasculosclerotic changes in individuals of the second generation and our ability to detect them so early in life warrant the deduction that such changes begin during development *in utero*—in other words, the children are born with a degree of arteriosclerosis.

Clinical evidence of arteriosclerosis in the living subject is considered ample when two or more of the following findings are demonstrable: undue palpability of radial and other vessels, visible pulsation in the brachials, undue tortuosity in these, the temporals, and other vessels, including the conjunctival vessels, undue accentuation of the second aortic sound and the determination of the functional worth of the heart muscle. To these must be added an estimation of arterial tension with a suitable apparatus, though alone it is of but little value in determining the presence of arteriosclerosis.

A detailed description of the methods usually employed in studying the cardiovascular apparatus would be superfluous here. But the palpation of vessels is such an important procedure in determining the presence of arterial thickening that I may be pardoned for calling attention to the necessity of accuracy in technic, even in the frequent and time-honored practice of feeling the pulse.

Not only the radial, but the brachial, temporal, posterior tibial and dorsalis pedis, should be palpated and compared, right and left, in our search for vascular changes. Sahli's three-finger method is invaluable in estimating the qualities, tension, etc., of arteries; but in determining sclerotic changes in them it is not to be recommended, because sensation coming in from three fingers is more dispersed than when only from one. In order to determine the sclerotic changes, one should employ, as a rule, one, never more than two, fingers, and two only in cases in which the tension is so great as to interfere with firm palpation with one finger. In counting the pulse, it matters little whether one feels with one's finger-ball or one's finger-tip; but in feeling—in palpating—the vessel-wall with only the ball early and even decided changes may be entirely overlooked. One should, therefore, use the finger-tip in palpating arteries, because the tip is more sensitive than the ball, has less subcutaneous tissue, and more readily adjusts itself to the vessel.[6] The tip of the finger should be placed perpendicularly to the vessel at first lightly, to become aware of pulsation, then with gradually increasing pressure one should roll or attempt to roll the vessel. A moderate-sized artery, such as the temporal or radial when not thickened, is felt to collapse under the increasing pressure and it is with difficulty differentiated from adjacent structures.

When such a vessel is thickened—sclerosed—the wall remains more round, the finger-tip glides over its rounded surface, and one feels a degree of rigidity not present in normal arteries. Sclerosing arteries are frequently unduly tender to firm finger-tip pressure, more so than adjacent structures, the unpleasant sensation persisting at times for several minutes after the pressure has been removed, a point frequently mentioned by patients. As the finger-tip has less subcutaneous tissue than its ball (one reason why it should be employed), it is evident that its applied pressure should be at a point along the course of a given artery where it lies directly over bone and free from overlying muscle. Figures 4 and 5 represent two methods of finger-tip palpation of the radial artery.

In my first communication, I referred to vasculosclerotic changes as a sort of connecting thread between the syphilitic and his progeny. In my studies of many individuals and families on which that and this communication are based, a degree of such changes out of all proportion to the years is the one preeminent clinical fact discernible in the individual who has acquired syphilis, and it is the one significant clinical fact discernible in his children and his children's children. It is, probably, the main cause of the frightful antenatal and postnatal mortality among such progeny; probably the main cause of their lessened expectancy in life; of their proneness to disease—to degenerative and involutional changes; to the so-called functional nervous disorders and the underlying cause of tuberculosis in them—for is not the blood—the life thereof?

Admitting vasculosclerotic changes to be even a frequent correlation of the scaphoid type of scapula, is it not incumbent on us to search for and establish its cause and that of its other correlations? My studies, extending over a period of more than three and a half years, indicate far-reaching ramifications of the scaphoid type of scapula and its correlations—a rather definite syndrome in both general and special pathology. The frequency of what may be called the scaphoid-type of scapula syndrome in our population, occurring in all branches of society, seems to postulate a single cause and one sufficiently potent to modify profoundly the growing organism from its very foundations. Thus far I have found no other cause than syphilis in the ascendants, but my studies have been too brief and too incomplete to enable anyone to draw definite conclusions from them and apply them to every individual in whom this syndrome may be found. This seems certain, however: nothing occurring in the life of an individual after his birth can give him the scaphoid type of scapula and its correlations.

Before one may determine the significance of this syndrome in any individual, the individual must be studied from every angle and in a comparative way with the members of his own family and with average members of his community. With the use of modern refinements in clinical investigation; with the use of laboratory methods, merely to confirm and to control clinical deductions; with patient study of individuals and of the individuals of families rather than the histories of individuals of families on the part of many workers, the ultimate cause or causes, as well as the hereditary, clinical and pathologic significance of the scaphoid type of scapula and its correlations may readily be determined.

My studies thus far warrant my saying at this time that such research on the part of many workers will undoubtedly lead to more complete recognition of syphilis and of its blighting influence in the individual affected, in his children, and in his children's children. Out of such recognition, let us hope a sane prophylaxis may be developed, whereby much suffering which now comes to humanity from this insidious enemy of the human race may in succeeding generations pass away from the earth forever.

INGUINAL HERNIA FOLLOWING APPENDECTOMY*

ALANSON M. POND, M.D.
DUBUQUE, IOWA

During the past twenty-five years the pathology of appendicitis has been cleared up and the operative treatment has been elaborated and commented on so extensively that the entire country has been thoroughly informed of the gravity of the condition and equally convinced of the necessity for surgical treatment. Dexterous surgeons perform appendectomy with such marvelous simplicity and rapidity before admiring classes and visitors that the latter are impressed with the ease and rapidity of the operation, and fail utterly to realize that there is a surgical reason for every step of this procedure, or that this seasoned operator has worked many months or years to perfect his technic and to study out his attack along the lines of proper surgical anatomy. They see only the simplified application of correct principles.

The result of this is that surgery of the vermiform appendix is more extensively practiced than ever before, and consequently the profession is becoming more and more conversant with the sequelæ of appendectomy, both immediate and remote. It is evident that not every case of survival after the operation cannot properly be called a recovery. Many patients who do not die from the operation are disabled; for the sequelæ of all abdominal operations are increasing. This is not due wholly to the increase in surgery, but partly to the increase in the number of the men who do surgery. It is purely a matter of personal equation—of ignorance or disregard of surgical or anatomic principles. When a thorough knowledge of surgical pathology dictates the operation and a perfected mastery of surgical anatomy directs it, the results, both immediate and remote, were never so satisfactory as at present.

---

* Read in the Section on Surgery of the American Medical Association, at the Sixty-first Annual Session, at St. Louis, June, 1910.

Among the commonest sequelæ is hernia; when this is hernia of the abdominal wall or of the scar, it is as a rule the result of delayed union, impaired healing, or of improper suturing. Delayed union may result from a drain or from an infection of the line of incision subsequent to operation. Improper wall suturing may occur through undue haste, or through ignorance of the surgical anatomy of the structure penetrated.

This paper, however, deals only with inguinal hernia. The following case illustrates the type:

H. W., aged 24, was operated on Sept. 26, 1900, for an acute attack of appendicitis; wound closed without drainage; mural abscess evacuated on eighth day; recovery apparently complete on the twenty-first day. Patient resumed work on the twenty-third day after operation. On Feb. 2, 1901, patient presented himself for examination. Long broad scar in right hypogastrium showed evidence of suppuration. Palpation of wall failed to reveal weakness in line of suturing or in abdominal wall. Right inguinal hernia complete, oblique. First noticed as a sense of weakness about Jan. 1, 1901; then, lump appeared in groin, which eventually descended in to the scrotum.

This was an inguinal hernia that followed an appendectomy within four months, and the first of a series of cases that I have seen.

When right inguinal hernia appears as a sequel to an appendectomy, it can usually be ascribed to an infection of the abdominal wall, to destruction of the nervous supply of the inguinal canal, or perhaps to both. Infection of the wall above the deeper layer of the superficial fascia is not destructive of the essential structure of the abdominal wall, but if the intermuscular spaces are invaded there results a serious damage to the muscles as well as to the nerves.

Mural abscesses have been a very common complication of simple wound repair, and were ascribed formerly to improperly prepared suture material. A study of the bacteriology of the skin, however, will lead direct to the cause. The pyogenic organisms most commonly found in mural abscesses is the *Staphylococcus epidermidis albus* of Welch, and where mixed infection occurs, the staphylococcus is usually combined with the *Bacillus coli communis*. Hence the inference is natural that this infection comes primarily from the skin, either from puncture of the needle from unnecessary handling or from improper protection.

It is common experience that mural abscess almost invariably follows any inordinate hemorrhage from the needle wound, and not infrequently this hemorrhage is so sharp that it requires a compression ligature to control it. The blood from this puncture invites invasion by the bacteria of the skin, and the closed wound fulfils all the requirements of an incubator; and in about seven or eight days, just when the patient ought to be recovering, a mural abscess is discovered; repair is delayed, and destruction of the integrity of the abdominal wall is reasonably certain. This interrupted recovery is decidely discomforting; but it becomes absolutely humiliating if in three to six months the patient returns with a right inguinal hernia as a remote result of the infection. Absolute hemostasis, or, if bleeding is unavoidable, the removal of blood by a small wick of gauze emerging from the lower angle of the wound, to be removed at the end of twenty-four hours, will prevent the blood-clot effectively and remove any possibility of mural abscess with its train of dire consequences.

The nerve-supply of the right lower abdomen may be damaged by sepsis, or by ruthless disregard of the course of these nerves in outlining the incision. The nerve supply of this region is obtained from the iliohypogastric and the ilio-inguinal. These nerves arise from the first lumbar with a contribution from the twelfth dorsal; they pass forward over the psoas muscle and penetrate the transversalis above the crest of the ilium and spread themselves in a fanlike manner between the internal and external oblique, perforating the external oblique from 1½ to 2 inches to either side of the linea semilunaris. After the perforation of the external oblique they become merely cutaneous nerves of sensation. But during their course in the intermuscular layer they supply the external oblique, internal oblique, transversalis, intercolumnar fascia and the conjoined tendon. Please note that the above-named structures comprise the anatomy of the inguinal canal.

Any surgical treatment that necessitates the exploration of the abdominal cavity, requires full knowledge of the structures comprising the wall of that cavity; the mere names will not suffice, but the nerves supplying the layers, their course, and distribution must be known, recognized and protected. It is not the object of this paper to discuss the various incisions preferred by surgeons in gaining access to the abdominal cavity; suffice it to say that any method or site of an incision which does not compromise the integrity of the wall, by reason of injury or destruction to important tissues, is surgically justified; and that any incision which has not that object in view is never surgically justified even if recovery without sequelæ should result.

The percentage of inguinal hernia following appendectomy is not large; but if it occurs at all, the proportion is altogether too large since the sequela can always be prevented by surgical knowledge of the structures of the abdominal wall and by surgical precaution to prevent wall abscess.

1222 Locust Street.

ABSTRACT OF DISCUSSION

DR. E. WYLLYS ANDREWS, Chicago: We are familiar with the occurrence of femoral hernia as a sequel to operation done for the cure of inguinal hernia or *vice versa*. There is dilatation of the one canal by reason of pulling upward or downward of its boundary. In the case reported by Dr. Pond there was evidently a weakening of this canal by the injury done to its upper boundary. It is probably true that we must revise our ideas of the pathogenesis of inguinal hernia to a considerable extent, from the important information recently obtained from the preformed sac, which it is now known exists not only in the well-known and well-recognized congenital hernia, but in a very large percentage of so-called cases of traumatic hernia. So that in traumatism we recognize only a slightly exciting cause or, as many of our corporation lawyers are now claiming, a non-existent cause. It may be that Dr. Pond's conclusions were based on an insufficient number of cases, if we lay a great deal of emphasis on the preformed sac as an element in all inguinal hernias. I cannot help recognizing the importance of the anatomic distribution of the nerves and the occurrence of the atrophic changes, which were probably all present in Dr. Pond's case.

Simulation of Pulmonary Tuberculosis.—The compulsory military service in Europe leads to considerable malingering to escape or shorten it, and the latest device of the kind is the simulation of the early signs of pulmonary tuberculosis. Dr. Batier has recently reported three cases of the kind in which the symptoms of the feigned disease promptly subsided when the patients were sent to the guard-house for their attempt to deceive the medical authorities. His communication is published in the *Tribune Médicale*, April 16, 1910, page 241.

PHRENITIS PROSTATICA*

JAMES F. PERCY, M.D.
GALESBURG, ILL.

Affections of the mind proceeding from the pathologic prostate gland have had no place in the literature of disease until 1907.[1] Before this date, the prostate had been considered only from the standpoint of urinary obstruction and infection. It is the purpose of the present paper to emphasize the surgical importance of the prostate along medicolegal lines. I can do this best, perhaps, by detailing the history of a recent case. By way of preface, permit me to say that this history is not an uncommon one. The difficulty has been to attribute the cause of the trouble to its source, viz., the diseased and usually hypertrophied prostate.

Mr. X, aged 66, has a history of prostatic irritation extending over a period of ten years; voids urine three to four times during each night; does not use catheter; amount of residual urine unknown; urine normal except for occasional hyaline casts; rectal examination shows large, soft prostate of estimated diameter of two and a half inches, with length of three inches; blood-pressure, 180; temporal vessels, tortuous; radial pulse, normal; no evidence of spinal cord or brain lesion. The patient is in good general health, except that he has called himself a sufferer from "dyspepsia," for many years. He has always had the reputation of a model citizen; is honest, truthful, and of good financial standing, and of exceptional judgment on general affairs; the father of three healthy children to whom he is devoted, as he also was to his wife when alive. About a year ago he began to furnish material for the scandalmongers of his city, because of his illicit sexual relationship with a woman of questionable character. This woman's domination over him seemed to be complete, even to the extent of transferring a portion of his property to her. He will go to any length, as far as untruthfulness is concerned, to protect what he calls the reputation of the woman in question. Only in this respect has the man's character changed. In all others, he is the same model citizen and father that he has always been.

I cannot report the surgical history of this patient. But he like many of those similarly afflicted, refused operation for fear that it might rob him of his excessive sexual desire. Others in my series of cases, however, supply the necessary postoperative history to show that a chain of certain definite symptoms can accompany hypertrophy of the prostate. These symptoms are usually manifested by immoderate sexual indulgence late in life, together with a distinct mental symptomatology along the lines of the psychic life of the afflicted individual. Unfortunately, these manifestations often occur in a form to discourage the belief that man was created in the image of God.

One of my patients, a physician, aged 68, with a large soft prostate and urinary obstruction, would not use a catheter except when compelled to. His most frequent method was to empty his bladder during intercourse with his wife, aged 64. The latter suffered from an intractable form of leucorrhea. Removal of this man's prostate cured his abnormal sexual life.

Another man, aged 74, first consulted his physician because of the waning sexual desires of his wife, aged 68. He wanted medicines from the family physician to restore her sexual powers. The wife begged the physician not to give her anything, but to do something for the husband. His history showed that the sexual congress averaged from two to four times every night. The family physician suspected some form of spinal cord or brain lesion, and the patient was sent to me for diagnosis. Nothing was found beyond what one would expect in a well-preserved old man. He was very much surprised when told that his sexual activity was absolutely abnormal, and that if persisted in, he would probably develop some form of spinal cord disease. This man had a very large prostate, and its removal stopped all of his abnormal sexual symptoms.

Many of these patients are cunning in a bunglesome way in their efforts to conceal their unappreciated affliction from the family and friends. In a former paper, I described, among others, two cases, in one of which the patient almost disrupted his home and the community in which he lived because of his sexual relationship with some of the lower animals. This man was a lawyer of good standing who had served a number of terms on the bench. He was absolutely cured by the removal of a very large, soft prostate, and has remained well, now six years. The other patient was a progressive business man of the intellectual type, who had scandalized the community by his unlawful relations with negro women. An abscess of his prostate, which destroyed half of it, and caused an atrophy of the remainder, cured him. Subjects of this disorder can be found in many of the almshouses, particularly, and in the government soldiers' homes, and they are frequently admitted under the mistaken diagnosis of senile dementia. Regardless of where or when found, whether in an insane asylum or in their homes, they always form a disgusting, but nevertheless pitiable, chapter in the phenomena of sexual excess. These are the men who, at 80 years of age, marry girls of 16. They also become the easy prey of designing women who are not 16. The legal documents which they sign, especially when they attempt to divide their property, are often biased by influences that have back of them a perverted mind made so by a diseased prostate. Two celebrated cases which occurred in this country within the last two years, are in this class. I am assured by those in a position to know that both of these men suffered from the delusional sexual irritation which is characteristic of this condition in a certain as yet unknown percentage of those suffering from an enlarged prostate.

To quote partially from my former paper:

> It is possible that a certain proportion of the sexual neurasthenics and sexual perverts may have as an explanation of their mental aberration, a pelvic rather than a brain pathology. Certain it is that an earlier recognition of disease of the prostate and its appendages, with the mental symptoms that may accompany it in the young or old male, would, in a certain proportion of cases, save the pride of the family of the sufferer, and prevent the moral health of the community from being undermined. The local conditions in the prostate seems to set up an irritation which is expressed through the sympathetic and cerebrospinal symptoms; and out of this will grow visions and mental vagaries until the old man becomes a prey to all sorts of phantasms that finally make his life a mere sexual fetish. Before a diagnosis of sexual neurasthenia or of senile dementia is assumed to be the final word, the possibility of prostatic disease should be eliminated, and if this is found, especially the large hypertrophied gland, its excision will show in a large proportion of the cases that the problem was a surgical rather than a neurologic one.

The symptoms so briefly enumerated above have back of them as yet an undescribed pathology. It would seem to me, however, that the tardy recognition of the thyroid as a cause of certain classical symptoms was to be paralleled when those of phrenitis prostatica were referred to their proper origin. The microscopic anatomy of a gland does not show its vital relationship either to other glands, or to the general economy. This is true of the thyroid, and I believe it to be true, also, of the prostate. No work that I am familiar with has attributed to the prostate an extra, or an internal, secretion; and yet, in ten out of the twenty-five cases 40 per cent. on which the studies in this paper are based, the patients had large, juicy prostates. In addition to this, all of the 10 had thick capsules, making their removal by the perineal route comparatively easy. The youngest of these ten patients was 63; the oldest, 75.

* Read in the Section on Surgery of the American Medical Association, at the Sixty-first Annual Session, at St. Louis, June, 1910.

[1] Tr. Western Surg. and Gynec. Assn., 1907; Illinois Med. Jour., November, 1908.

Shäfer has shown that the cortex of the suprarenals is probably a separate secreting gland tissue which may have a close relation to the sexual organs and to the pigments of the skin. Whether the changes incident to the enlarging of the prostate during the sunset period of life in the male augment or inhibit an unknown secretion, is difficult to say. Whether the hypertrophy destroys, as is evident in some cases of thyroid (colloid) enlargement, or whether it increases this assumed internal secretion, is unknown. As is well known, however, the feeding of thyroid extract in certain hypertrophies of the thyroid stops the symptoms of excessive blood-pressure (uninhibited suprarenalism), which coexist with this form of disease in some cases. It is not difficult to assume that some such problem as this may be back of the symptoms described in the title of this paper.

"The thousand-mouthed succulent prostate," as Keyes has well named it, makes the problem of separating the various secretions that enter into the seminal fluid an extremely perplexing one. I have had under way investigations that, it is to be hoped, will aid in the elucidation of this subject. It is possible that these investigations will show that the seminal vesicles have a realm of function that will suggest the suprarenals when the kidney is considered, or even the parathyroids when the thyroid is studied. Glands are the highly differentiated islands of the body, where the physical and psychic life come in touch with vital processes through the streams of nerves and vessels. The prostate is the sexual solar system. In the young man, when the functions of this gland or its environs become perverted from an infection or a neurosis, we have many times what Casper has termed sexual neurasthenia. When this irritation becomes pathologic to the degree found in hypertrophy of the prostate, we have a distinct and heretofore undescribed diseased condition of the mind that merits the title given it above. This condition, which is not senile dementia, is cured by excision of the prostate. Sexual neurasthenia, as it is found in those who are not old, usually has back of it some form of genito-urinary infection; while the senile hypertrophied prostate as a rule, gives no evidence of infection except in the occasional case in which the seminal vesicles contain pus not unlike the sealed tubes found in women suffering from salpingitis. The sexual neurasthenic, the young sexual pervert, adolescent sexual precociousness, and the senile sufferer from phrenitis prostatica, however, may be affected with one and the same thing, one condition being but a varying degree of the other; any one, or all of them, merely serving as a pelvic electric button which, depending on the stage of life in which the trouble manifests itself, merely serves to ring up the psychic life of the sufferer in various ways along the line of diminished sexual balance.

In closing, permit me the following word of argument. If the removal of postnasal adenoids can transform the mental, moral and physical life of a child from the abnormal to the normal, is it beyond argument that the removal of the prostate at the other extreme of life will not produce the same good results? Embryologically, adenoids are but an aberrant branch of the nervous apparatus, and the same primitive findings regarding the prostate place it, according to Walker, as a part of the sexual system. Remembering this, we need not be surprised that adenoids, when present, give rise to characteristic mental conditions, or that the hypertrophied prostate may cause a train of disgusting mental phenomena that also can be removed by well-applied surgery.

Whether *phrenitis prostatica* is due to an over supply or an undersupply of an as yet unknown internal prostatic secretion; whether it is merely an obstruction, developing mental symptoms by irritation and pressure of the nervous supply to the gland itself; or, whether the prostate, with its assumed internal secretion, is thrown out of rhythm with some other gland by the hypertrophy; whether this "other" tissue is the cortex of the adrenals, which some laboratory workers have shown to be hypertrophied in the lower animals possessing extraordinary sexual development, and "atrophied when the sexual power was low;" or, "whether it is due to some abnormality in the involution of the sexual organs"; or, whether, after all, the trouble is a central one following loss of control by the brain of the immoral impulses of our bodies, I do not know. But I do know that excision of the hypertrophied prostate, in the presence of the mental symptoms above described, will restore the unfortunate possessor of them to health.

ABSTRACT OF DISCUSSION

Dr. Harold N. Moyer, Chicago: The province of the Section on Nervous and Mental Diseases has been seriously invaded by the two papers on the program of the Section on Surgery, one proposing the cure of mental troubles by the removal of the prostate and the other proposing the cure of dementia præcox by removal of the thyroid. It is not questioned that the diseased prostate may cause symptoms such as Dr. Percy described and that these symptoms will in large measure be removed by removing the prostate. Unfortunately it leads into a rather discreditable chapter in the domain of surgery, in which surgeons have cut off and cut out for the cure of nervous disorders.

I would criticize Dr. Percy's paper in many particulars; in the first place, the title of the paper, "Phrenitis Prostatica," inflammation of the mind due to the prostate. The term "phrenitis" has not been used by an alienist for seventy-five years. Dr. Percy means a certain collection of mental symptoms that have their origin in the prostate, and are undoubtedly reflex in character. Some of the arguments he advanced, I believe, are not sound, although his conclusions are sound. In the cases of sexual perversion, or those in which there exists the *symptom-complex described, one should not* at once excise the prostate and expect to effect a cure. One should wait a few days to be sure that the prostate is diseased, because if it is healthy it will do no good to take it out. Next, one should consider if there is no other treatment for the diseased prostate but excision, or if there is any such thing as a stricture at the membranous urethra, granulation tissue in the sinus pocularis, and other things that might be responsible for the trouble and that can be relieved very greatly, at least, by some means other than removal of the prostate gland.

I think, however, that the paper is a lesson for the surgeon as well as for the neurologist. The surgeon should know that certain things may come from the diseased prostate originally, although in exceptional cases, and for the neurologist to know that he is apt to neglect some things on the physical side of the case. No neurologist should attempt to treat sexual perversion or neurasthenia when symptoms point to the genital tract without an examination of that tract. The two things are often inextricably mixed, so that sometimes we have a strong prostate overcoming a weak brain, although if the brain is sound it will usually take care of the diseased prostate.

DR. J. F. PERCY, Galesburg, Ill.: I am sure that every practitioner of experience has encountered these cases, and it is possible that you will meet with more of them now since your attention has been called to this factor. If phrenitis prostatica does not quite answer in the way of nomenclature, will not Dr. Moyer give a term that is just right? I have tried to get a term that seemed more correct than "phrenitis prostatica," but a friend, an eminent Greek scholar, after reading my paper, gave me this title, with the assurance that it was entirely correct.

REPORT OF THE COMMITTEE FOR THE STUDY OF THE RELATION OF TUBERCULOSIS TO DISEASES OF THE EYE*

WILLIAM H. WILDER, M.D.
Chairman of the Committee
CHICAGO

This committee was formed for the purpose of studying in a cooperative way the relation of tuberculosis to certain diseases of the eye, the etiology of which is often obscure.

As was stated in the preliminary report, it was thought that a number of observers might accumulate enough data to draw conclusions that might not be warranted by the limited observations of a single individual.

Those who were interested in this work agreed to study their cases according to a plan that was prearranged, and to keep records on blanks prepared for the purpose, so as to facilitate compilation.

This plan of study contemplated a thorough physical examination of the body to determine, if possible, the etiology of the eye disease. If, in this examination, no reasonable etiology could be determined, other than that the patient gave evidence of having either active or quiescent tuberculosis in some part of the body, it would be strong presumptive evidence that tuberculosis played some rôle in the causation of the eye disease.

Unfortunately, it is difficult to control clinic and dispensary patients as one would like; and it is also difficult to exclude syphilis, blood conditions, autointoxications and other factors, in order to get perfectly definite results in such a problem. But if we can place any reliance in the tests that have been proposed by Koch, Wolff-Eisner, Pirquet and Calmette, it is not difficult to determine whether or not a person is tuberculous, even in the absence of well-defined physical signs.

It is one thing, however, to show that an individual is tuberculous and quite another to prove that the lesion of the eye that he has is tuberculous; and yet, while there may be lacking the positive proof, the presumptive evidence may be strong.

Such is the case when, in addition to the general reaction from the subcutaneous injection of tuberculin, there appears a reaction in the affected eye, manifested by a conjunctival or ciliary injection or an aggravation of the original trouble. This has been done in many cases, when feasible; in many of them we had to rely on the physical examination or the simpler cutaneous test of Pirquet.

There has been a growing distrust and fear among ophthalmologists of the use of the conjunctival test, proposed by Wolff-Eisner and Calmette, that I think is not altogether well founded.

Most of the members declined to make use of the Calmette test in this study, because they consider it dangerous. It is true that certain ill effects from the use of tuberculin in this way have been observed, and the alarm has been sounded by several oculists of note, but I am inclined to think the reason for the bad results is that the solution has been used too strong at first. It is as necessary to know just what strength one may use with safety in the conjunctiva as it is to know what dose one may safely administer subcutaneously.

Within the past year I have made observations in a number of cases of eye disease that I had reason to believe were tuberculous in nature, and found that not only did the patients tolerate tuberculin administered in the eye in small doses, gradually increased, but they actually improved as I approached the dose that would excite a mild reaction. To be on the safe side, the first dose would be 1/1000 mg., gradually increased until in some cases 1/10 mg. would be employed, a dose nearly equal to that ordinarily employed in the Calmette test.

These cases will be made the subject of a personal communication later, after further observation and study.

The following members of the committee have submitted records of cases that are included in this report: Drs. George S. Derby (Boston), Charles Stedman Bull, Arnold Knapp (New York), W. C. Posey, George E. de Schweinitz (Philadelphia), Harry Friedenwald (Baltimore), L. W. Dean (Iowa City), and W. H. Wilder.

For various reasons, other members of the committee were prevented from engaging in the work, so that the showing is not so large as we had hoped to have it, but altogether we have 144 cases to report that have been studied with a view to determining whether tuberculosis played any rôle in the etiology. These cases have been classified as follows:

Blepharitis	3
Dacryocystitis	2
Follicular conjunctivitis	5
Phlyctenular disease of conjunctiva and cornea	12
Scrofulous pannus	
Keratitis (deep and nodular)	
Interstitial keratitis	18
Episcleritis	4
Scleritis	3
Sclero-keratitis	22
Chronic iritis	3
Chronic iridocyclitis	7
Uveitis	6
Chorioiditis	5
Chorioretinitis	3
Total	144

BLEPHARITIS

BULL: CASE 1.—Boy, aged 4; in upper right lid a small nodule appeared, which increased in size to that of a small pea and became red and painful; no enlarged glands; lungs and other parts normal. Von Pirquet test negative after three trials. Subcutaneous test, decided general reaction; temperature 100.4 F.; no local reaction.

CASE 2.—Girl, aged 15, had a small nodule in middle of lower right lid that extended into conjunctiva, ulcerated and bled easily. Von Pirquet test negative; subcutaneous test positive. Temperature 100.2 F.

These cases were regarded as tuberculosis of the lid.

WILDER: Girl, aged 6, with blepharitis ulcerosa. Tonsils enlarged, adenoids present, superficial lymph glands enlarged. Reason to believe that child was tuberculous, but three v. Pirquet tests negative.

DACRYOCYSTITIS

WILDER: CASE 1.—F., aged 19; fistula in tear sac. Lymphadenopathy. Marked reaction to v. Pirquet test.

CASE 2.—F., aged 9; chronic dacryocystitis; appears tuberculous. Pulmonary examination negative. Three v. Pirquet tests negative.

FOLLICULAR CONJUNCTIVITIS

WILDER: Five patients, ranging in age from 1½ to 15 years. In all these cases perceptibly enlarged lymphatic glands. In all pulmonary examination negative; v. Pirquet test positive in three and negative in 2.

PHLYCTENULAR CONJUNCTIVITIS AND KERATITIS

DERBY: Eleven patients, 9 under 14 years of age, 1, 28 and 1, 30. In 8 unmistakable clinical signs of tuberculosis; 5 of the lungs, 1 of the spine, 1 of the knee and spine, and 1 of the cutaneous test, 5 mg.; temperature, 101.8 F.; positive; no reaction in eye.

---

* Read in the Section on Ophthalmology of the American Medical Association, at the Sixty-first Annual Session, held at St. Louis, June, 1910.

de Schweinitz: Girl, with form of retinal disease, with extensive exudate, simulating tuberculous disease; subcutaneous test negative.

Wilder: Female, aged 18, failure of vision of both eyes at age of twelve; fair health; no evidence of syphilis; chorioretinitis in each eye; media normal. R. V. = 10/200; L. V. = 5/200. Von Pirquet test three times negative.

Summary.—Six cases of chorioiditis, in 4 of which subcutaneous test gave a positive general reaction, with local reaction in the eye in 2. Two cases of retinitis or chorioretinitis, in which tuberculin tests were negative.

In trying to arrive at some definite conclusions as to etiology in a group of cases like the foregoing, one should consider carefully the relative value of the means and tests employed in the examination of such cases. If active tuberculosis is present or has been present in lungs, joints or bones, sufficient to cause any marked changes, the condition may be discovered with all reasonable probability by careful physical examination. But if from 90 to 98 per cent. of all persons who have reached 60 years of age have been at some time infected with tuberculosis, as is claimed, then very many have suffered so slightly as not to present signs of the disease that can be determined during life by our methods of physical examination.

If from 90 to 95 per cent. of all persons who have passed the adolescent period of life will respond actively to the sensitive cutaneous test of v. Pirquet, as is claimed, it helps to confirm the statements of the pathologists as to the ubiquitous nature of the disease. This being so, in a given case of eye disease, one could place little reliance on this test as determining the actual etiology of the eye lesion without first positively excluding all other factors, and this is not always possible.

The same criticism would apply to the Calmette test which, on account of its danger in diseased conditions of the eye, one would hesitate to use for ophthalmic diagnosis, even if one eye were sound. Response to this test might prove, as is claimed, the existence of active tuberculosis in some part of the body, but would not necessarily determine the nature of the eye lesion.

In the test by subcutaneous injection of tuberculin, the same difficulties are encountered. A general reaction following this test would only prove that the individual is tuberculous (excluding syphilis, leprosy, actinomycosis), which might be done by the simpler v. Pirquet or Calmette test. If, however, a local reaction in the diseased eye occurs, manifested by ciliary injection, conjunctival redness, or marked aggravation of the previous condition, we have strong presumptive evidence that the lesion in the eye is tuberculous. But the eye may be so inflamed as to prevent us from observing whether or not there is increased reaction, so that the test, if made, should be made when the eye is in a comparatively quiet condition.

Again, this raises the important question whether such structures as the cornea, sclera and uvea may not be thrown into a diseased condition by the toxic substances from the bacilli in a distant focus of tuberculosis, reaching them through the blood and lymph channels, without the presence of the micro-organisms themselves in any part of the eye. This being the case, might we expect a local reaction in the eye, even if we encountered a general reaction with the subcutaneous test?

An interesting feature of this series of cases is the frequency of association of tuberculosis in some part of the body with eye conditions, such as phlyctenulosis, deep and interstitial keratitis (non-syphilitic), and sclerokeratitis, and the frequency of local reaction in the eye in such cases, with the use of the subcutaneous test.

In 59 cases of keratitis, episcleritis, scleritis and sclerokeratitis, 56 gave positive evidence of being tuberculous, either by physical examination or tuberculin tests. In 27 of these cases subcutaneous tests were made, and of these 22 were positive as to local reaction in the eye.

If it were possible to study all such cases that appear in a year or two in several large clinics or eye hospitals, we might arrive at some instructive conclusions as to the frequency of tuberculosis as a cause of such diseases.

ABSTRACT OF DISCUSSION

Dr. John Green, Jr., St. Louis: I observed that, under the heading "keratitis," reference is made to "nodular" keratitis, "nodular" infiltrates, etc. In the summary, Dr. Wilder speaks of twelve cases of "nodular" keratitis, in which eleven showed evidence of tuberculosis. It seems to me that the term, "nodular," in connection with tuberculous corneal opacity, should be abandoned, in view of the fact that "nodular," qualifying "keratitis" or "opacity of the cornea," has come to possess a very definite clinical significance. Groenouw has used the term "nodular" in describing a peculiar chronic affection of the cornea, characterized by the presence of discrete subepithelial masses in the central portion of the cornea, and the term has been applied by subsequent writers in describing this condition. The disease is extremely rare, there being less than fifty cases in the literature, and in less than ten of these has there been found any evidence of tuberculous origin. Confusion is bound to arise if cases such as are described in the report, which bear no relation to "nodular" keratitis or to "nodular" opacity of the cornea, are nevertheless designated as "nodular."

A CASE OF EPISTAXIS

Dr. EDMUND R. BLAAUW
BUFFALO, N. Y.

The article about epistaxis in The Journal, April 30, induces me to relate the following case:

On March 25 a 19-year-old boy consulted me for very severe headache. About two weeks previously he had influenza and four days previously his head began to pain him, so that sleep was impossible; his nose began to run at the same time. Percussion on the left frontal sinus was painful; also pressure in the left upper inner orbital corner. The left middle turbinate was swollen and, after depletion by cocain and epinephrin (adrenalin), pus came from below and above the turbinate. My diagnosis was left frontal sinusitis and ethmoiditis. The symptoms had not improved markedly the next day, so I removed the middle concha. No abnormality was noticed, the headache was controlled, and packing removed the following week. Eight days after the operation slight nosebleed occurred, but the cotton plug soaked in hydrogen peroxid solution stopped it entirely. Three days later all packing was removed, and the patient told to keep quiet. In the night of April 6 the patient suffered from a profuse hemorrhage. His family physician and a colleague gave atropin subcutaneously, but were unable to control the bleeding, even after tamponing the posterior nares. On my arrival I found the amount of blood lost considerable, and becoming alarming. I removed the posterior tampon as it only caused irritation and the place from which the bleeding came was in the anterior part of the nostril. But plugs soaked in hydrogen peroxid had no effect; epinephrin had been used before without success. No drugstores were open during that night. The only calcium preparation at hand was calcium chlorid, which we gave liberally. The only effective means proved to be keeping the patient as quiet as possible and plugging the nostrils with ordinary non-absorbent cotton, which contains fat (suggestion by Dr. Hengerer), soaked in mercuric chlorid solution. Dr. Scott Renner, who was asked to come, found the bleeding stopped and ordered morphin subcutaneously.

The patient was transferred to the hospital early in the morning, and made a good recovery, so that four days later all plugs were removed; the patient was kept in bed thirty-six hours afterward; a new hemorrhage started, without a known cause, and the patient lost about one liter of blood before I could reach him. Tampons with a solution prescribed by Dr. Renner (equal parts of antipyrin, 10 per cent. aqueous solution, and tannic acid, 10 per cent. spirituous solution) proved successful. The patient left the hospital three weeks after the first severe nightly hemorrhage. We have given him calcium lactate, which has been recommended for adenoid operations and tonsillectomy, and which, in the cases in which I have used it, seemed to make the blood more coagulable and the bleeding less abundant.

A remedy which was not used in this case, but which I find advocated by Dr. R. Lenzmann* is serum, as this contains the substances which bring on the coagulation. As plain serum cannot be had generally, antitoxin serum should be used with as low a quantity of "units" as possible.

This kind of nosebleed is due to an opening of an artery; it is therefore clear that epinephrin will do harm by raising the pressure in the smaller peripheral arteries and capillaries.

327 Franklin Street.

HYPEREMIA TREATMENT IN INFECTIONS OF THE BREAST

BERTRAM M. BERNHEIM, M.D.
Assistant in Surgery, The Johns Hopkins University; Assistant Surgeon to the Out-Patient Department, The Johns Hopkins Hospital
BALTIMORE

A previous communication[1] was devoted to the use of hyperemia as applied to the various forms of infection, such as boils, carbuncles, bone-felons, etc., usually seen in a surgical dispensary. Since that time this method of treatment has been continued along the same lines and with the same uniform success. But perhaps the most striking and gratifying results have been obtained in infections of the breast, and it is these that I wish to report now.

All grades of infections were treated, ranging from those of such severity that the patient was almost prostrated, down to the simple, but at times painful, caked breasts. Indeed, several patients were truly fit subjects for the hospital, but their absolute refusal to avail themselves of the privilege of the wards compelled us to treat them in the out-patient department.

The routine treatment is about as follows: When the patient is seen early in the disease and pus formation has not occurred, cupping is at once instituted for from fifteen to forty-five minutes daily, the breast between treatments being put up in a wet boric dressing, and nursing from it stopped. Abscess formation can frequently be prevented in such cases.

Unfortunately, however, most patients do *not* present themselves until an abscess has already formed and not infrequently ruptured. Wide incision is practiced in such cases, the patient being under ether or nitrous oxid. All pockets of pus are broken up with the finger and where necessary counter-radial incisions are made, followed by through-and-through drainage for twenty-four hours, with iodoform gauze. This is contrary to the usual rules of hyperemia treatment, in which drains are dispensed with, but the hemorrhage is rather profuse following incision, and, inasmuch as all our patients are ambulant, we have packed, more to avoid postoperative bleeding than for anything else.

In one or two instances I have used the cup immediately after the operation and with the patient still on the table, but in the severe cases this caused a considerable loss of blood and so much discomfort to the patient that now hyperemia is not instituted until twenty-four hours later.

At this time, with the drain still *in situ,* a cup at least 1 cm. larger than the entire breast is applied. A very moderate degree of suction is at first used—that is, a degree that causes no pain, only a slight blushing of the skin and very little bleeding. This is continued for about five minutes, then the cup is removed and the breast allowed to rest for about two minutes, following which the cup is again applied. This alternate cupping and resting is kept up until actual hypermia has been instituted for about fifteen to forty-five minutes, varying according to the condition of the patient, the condition of the breast, the pain and the bleeding, which is apt to be rather free at the first treatment.

The drains are usually firmly adherent at first, but if they are left in place during two or three cuppings, they become loosened by the flow of pus, milk and blood, and are then very easily removed, when the treatment is resumed. In cases in which they do not come away without much pain they are left until the following day.

It sometimes happens that the very large cup does not draw away the pus. In such instances the application of a small cup for a few minutes will have the desired effect, although if it is judiciously applied, severe pain may be caused. At the end of the treatment, a strip of wet boric gauze is loosely tucked in the mouth of the wound—simply to prevent closure—and the whole breast is put up in wet boric gauze, over which is placed a very loose bandage, thus allowing the breast to hang low, so that drainage by gravity will occur. The patient is now treated every day, occasionally twice a day, every two or three days, then every four or five days, until the process is healed.

It will thus be seen that this treatment differs in several respects from the rules laid down by Bier and his followers in the handling of these cases. Where they advise a small incision, we open widely. The small puncture is effective in the superficial abscesses, but in the deep, we have found that unless a generous incision is made, followed by breaking into all the pockets, and occasionally counter-incisions, one or more secondary operations are liable to become necessary.

Where the puncture wound is practiced the pack is unnecessary. Its use is self-evident, however, in the more radical operation, and we have discovered, much to our embarrassment, that the continued use of a loose pack just in the mouth of the wound is advisable.

In the old method of handling abscesses of the breast, tight bandaging was thought essential—in order to prevent milk-formation. Our patients have all been much more comfortable and we have had far better drainage since the loose bandage has been used, the breast being allowed to hang free. But aside from this, we believe it wise to continue the lactation, and as the cup aids in this, several (four) of our patients have been able to resume nursing on the affected breast after its restoration. No ill effects have resulted from this procedure, either to the child or to the mother, and we consider it an advantage, rather than a disadvantage.

When patients have been treated outside and have come in with a persistent sinus, the sinus has been laid open and packed twenty-four hours, following which the usual treatment has been instituted.

Lack of space prevents the publishing of individual case reports. It must, therefore, suffice to say that in the fifteen cases in which hyperemia has been used, the average duration of the disease, or rather the average duration of the infection, has been 19 1/3 days. The average number of treatments (cuppings) has been 7 1/5. Thirteen of the cases were in nursing mothers and four of these were able to resume nursing on the epithelium manufactured to take its place, provided the burn has not been deep enough to destroy all the epithelial cells in the hair follicles and glands of the skin. The exudate thrown out into the tissues and on the surface of a burn furnishes food for the development of new epithelial cells. It also furnishes a fertile field for microbic development.

---

*Lenzmann, Richard: Die Leben gefährende Krankheitszüstande, Ed. 2, 1909, p. 131.

[1] Bernheim, B. M.: Passive Hyperemia by Means of the Cupping-Glass of Bier and Klapp, THE JOURNAL A. M. A., March 14, 1908, p. 840.

If the exposed surface of a burn becomes infected and suppurates there will be scar-tissue, contractions and deformity as a result. Scar-tissue continues to form as long as there is a denuded surface with any form of irritation. Therefore the amount of scar depends on the extent of the burn and the time required in forming a new epidermis.

A degree of heat sufficient to destroy living tissue will also destroy pus-producing germs. So in burns which become septic the infection almost invariably comes from without or extends from the margins of the wound. The surface of a burn does not absorb easily. Its tendency is to exude. But later in the course of a burn severe enough to devitalize the tissue decomposition takes place and toxins are formed, some of which will be absorbed.

There are four things to demand attention in the successful treatment of burns, any one or all of which may be required in a given case; first, to combat shock if it exists; second, to relieve pain and nervous excitability; third, to prevent infection and to protect exposed living tissue; and fourth, to assist Nature in her work of repair.

1. Shock, which often occurs as a result of severe burns, is treated on general principles too well known to the profession to be discussed in this paper. Some one has said, "Shock is shock," meaning that regardless of its cause, shock must be treated in the same manner under all conditions.

2. To relieve pain and nervous excitability, it is usually necessary to give a hypodermic injection of morphin and atropin and then to immerse the burned area, if it be on an extremity, in cold water to which has been added a tablespoonful of bicarbonate or chlorid of sodium to the gallon. It is not necessary for the water to be ice-cold. A temperature of from 50 to 60 F. is preferable.

If the burned area cannot be immersed in water on account of its location it may be covered with a light smooth cloth which has been dipped in the solution; then by gently and continuously mopping this cloth the same result will be obtained.

This water-bath may be continued for some time or until the systemic effect of the morphin is manifest.

In institutions where trained assistants are always at hand the whole bath may be used and continued for many days if a large area of the surface of the body is burned.

3. Protection of the tissues and prevention of infection demands our greatest efforts and must be kept in mind from the beginning. Nature puts forth her greatest efforts, and the system will exhaust its entire resources to accomplish this end; but Nature cannot prevent the invasion of pus-producing micro-organisms—the surgeon can.

I wish here to condemn two things often done, and at least sanctioned by most of our text-books: first, puncturing blisters immediately after a burn and second, the use of carron oil and other remedies of its kind as a protecting dressing.

A blister is a non-irritating protection to the delicate underlying structures, and the surgeon can furnish none better. I have never known the raised epidermis to reunite with its base after the blister was punctured. In most cases it acts as an irritant and for several days following it causes serum to be poured out under the dressings to soil them and furnish a good culture-medium for any possible pus-producing germs which may be barricaded waiting for an opportunity to assert themselves.

Within a few days the epithelial cells in the deep glands of the skin will have accomplished their work of repair if properly protected by the blister.

If any blisters are accidentally burst with the epidermis rolled up or displaced to any degree, such epidermis should be treated as so much débris and at once removed.

We long since discarded the once popular idea that the most favorable symptom appearing in the course of any wound was the free flow of pus. With that theory any agent which hastened suppuration was the most plausible remedy for a burn. Balsams, oils and poultices were used. The last one of such remedies to be discarded by rational ideas is still mentioned and advised by some of our modern text-books, especially works on practical therapeutics, namely, carron oil (equal parts of lime-water and linseed oil). In my opinion this remedy has to its credit more unsightly scars and disfiguring contractions than all other empiric remedies combined; with all of its kind it should have been discarded many years ago and buried with the theory which prompted its use. I consider the following the ideal method of protecting the tissues and preventing infection.

When the patient is fairly comfortable the bath may be discontinued, and the burned area with the surrounding surface sprayed or mopped with peroxid of hydrogen. The entire surface should then be mopped dry with gauze. Then strips of gauze which have been previously soaked in the following solution should be applied over the entire area.

℞	gm. or c.c.		
Picric acid	4		ʒi
Alcohol	64	or	℥ii
Water	72		O.iss

Over this a thin layer of cotton should be applied. The dressings should be kept in position by loosely applied adhesive strips or a roller bandage. This dressing soon dries and may remain for several days, or until it becomes soiled; at which time remove all soiled or wet dressings, spray with peroxid, mop dry and reapply fresh gauze soaked in the picric acid solution.

After the third day the larger blisters should be opened and the fluid contents mopped away and fresh dressings applied. This treatment is applicable to all burns whose severity is not great enough to cause sloughing.

If sloughing does occur as a result of charred tissue or later as a result of infection, the dead tissue should be removed as rapidly as it becomes separated, and the underlying exposed surface sprayed with peroxid, and mopped with the picric acid solution; over this should be applied small strips of rubber tissue which have previously been soaked in 1:1000 bichlorid solution. The dressing should be finished as before suggested.

The picric acid solution, by its slight astringent action, limits the exudation of serum by constricting the congested superficial capillaries, and does not interfere with the development of new epithelium. Its germicidal action prevents infection, and in my hands has never produced any systemic toxic effect.

The rubber-tissue strips furnish a non-irritating covering to the denuded surface, and do not interfere with granulation in their removal. If the rubber tissue is applied in narrow strips, the edges being allowed to overlap, the dressing more perfectly conforms to the irregularities of the surface. This dressing should be changed as often as it is necessary to keep the surface clean and free from pus.

The treatment above outlined, allowing modifications in each individual case, is one which I consider most nearly ideal after ten years' experience in mining camps, dealing with every degree of this most common accident, from a slight scald to that produced by the most terrific mine explosions.

I have said nothing in this paper about the later complications and sequelæ, such as contractions, abscess formation, duodenal ulcers and those extensive burns demanding skin-grafting.

The object of this paper will have been attained if I have made clear the importance of treating all burns as wounds, and on a surgical basis, and that the prevention of infection and suppuration is by far the most important part of the treatment.

Therapeutics

PULMONARY TUBERCULOSIS TREATED IN HOME SANATORIA

The Medical Board of the Gaylord Farm Sanatorium, located at Wallingford, Connecticut, has just presented its annual report, and there is so much of general interest that it seems worth while to comment on it. This sanatorium is a state institution, supported by state funds and private charity. Most of the patients pay a small fee, but there is a weekly deficit for every patient treated. This institution has a capacity for 65 patients, and has just completed its sixth year of existence. It is located three miles from the small city of Wallingford, and fifteen miles from the city of New Haven, and from twelve to fifteen miles from Long Island Sound. It is situated on a hill not more than 400 feet above sea level, and has connected with it a large farm from which part of the produce, eggs, milk and poultry are furnished to the sanatorium.

The total number of patients under treatment during the last year was 166, the average number of patients under treatment at one time being 59. These patients came from all parts of the state of Connecticut, represented 15 nationalities, and came from 50 different occupations. Sixty-two of these patients remained at the sanatorium less than three months; of these 50 left the institution distinctly improved; in one the disease had progressed, and one died of acute pulmonary tuberculosis. One hundred and four patients remained at the Institution more than three months, the average stay being 161 days. Twenty-three of these patients who remained at the institution more than three months had the disease in its incipiency, and 21 of them were discharged with the disease arrested, 1 improved, and in 1 the disease was progressive. This result distinctly shows the advantage of early treatment of pulmonary tuberculosis in sanatoria. Seventy-five patients had the disease moderately advanced, of these 51 were discharged with the disease arrested, 11 had improved, in 11 the disease was progressive, and 2 died. Of 6 patients who had the disease far advanced, in 2 the disease was arrested, 2 improved, and 2 failed. Of the 104 patients who remained at the institution more than three months (incipient, moderately advanced, and far advanced), 74 or 71 per cent. of all, nearly three-fourths, were discharged with the disease arrested, and 14 more were distinctly improved. This is a record that is astonishing when not long since it was considered that patients with this disease must go to climates far better than southern New England before they could improve.

Ninety of the 104 patients who remained in the institution more than three months gained, on an average, 17.7 pounds as against 16.3 pounds in 1909 and 15.2 pounds in 1908. This is especially worthy of comment, as during the last eight months the patients had received no raw eggs, and have had no meat or eggs for breakfast, and the average consumption of milk has been a quart and a half pint daily. This gain is above the average of eight other leading sanatoriums, their average being 13.4 pounds, and the highest shown by any of them being 15.1 pounds.

From the very opening of this institution the medical board and the medical superintendent were a unit in believing that forced feeding in tuberculosis was a mistake. The over-working of organs and tissues to take care of enormous amounts of nutrition because one or two organs were diseased would seem an economic and physical mistake if it was not an actual physiologic error. Consequently good, nutritious food, but not forced feeding has been the character of the diet at this institution from its opening day, and Dr. David R. Lyman, the medical superintendent, has this year well demonstrated that even in earlier years the patients received too much food. The object is to furnish enough of each particular nutriment that is necessary to promote health, increase the weight of the patient, and to have a sound mind in, as far as possible, a sound body. Enormous amounts of food cloud the mental faculties and irritate and finally stagnate the functions of the body.

Since the institution was opened, 513 patients have been discharged prior to Jan. 1, 1910. Accurate information has been obtained concerning all but 17 of these patients. Up to Jan. 1, 1910, 105 patients who had the disease in its incipiency had left the institution. Of these 91, or 87 per cent. still have the disease arrested. Of the 293 patients who had the disease moderately advanced, 177, or 61 per cent. still have the disease arrested. Of 111 patients who had the disease far advanced, 16, or 15 per cent. still have the disease arrested.

These statistical results positively demonstrate that patients suffering from tuberculosis can have the disease well arrested and have it remain arrested, and perhaps be permanently cured, in the region, or at least in the climate to which they are accustomed. This is emphatically true if the patient, after the disease is arrested, is to remain and work in the locality where he acquired the tuberculosis.

Dr. Lyman is accumulating statistics which in a few years will be of great value in proving to the world what he has already proved to the medical board of this institution, viz., that patients who have the disease arrested thrive better, remain well longer, and are more permanently cured if they return to the occupations from which they came, *i. e.*, to the occupations to which they are used, and do not seek, under mistaken advice, some out-door work that is physically a hardship and generally causes them to work more hours, and for which the wage is inferior to inside shop, store, factory or office work.

The points of this report for practical application are:

1. Early diagnosis of pulmonary tuberculosis.
2. Treatment in nearby sanatoria when possible.
3. A sensible diet and no forced feeding.
4. The stay at the sanatorium should be long enough to arrest the disease thoroughly.
5. Unless some particular unfavorable conditions should prevent, the patient should be returned to the occupation to which he is used.

VALUE OF DRUGS NOT NOW OFFICIAL

This is a subject now timely for active discussion, as, soon, the Committee on Revision of the United States Pharmacopeia must decide which new drugs are of sufficient therapeutic value to claim recognition in the Pharmacopeia of 1910.

Prof. H. C. Wood, Jr., of Philadelphia, in a paper recently read in Washington, presents the subject in such a terse manner for general discussion that his own abstract of his paper is here presented. Dr. Wood says:

Progress in materia medica does not consist merely in changing our drugs; we must improve them as well. There is no reason for abandoning old and tried remedies for new substitutes unless there is some definite evidence that the new remedy possesses more power or is free from some objection of the older one. For instance, in the series of coal-tar anodynes we have had brought to the attention of the profession a large number of synthetic compounds even in the single group of the phenetidin derivatives of which we have a representative in the Pharmacopeia in acetphenetidin. It is beyond comprehension how substituting for the acetyl radical that of some other organic acid can alter the therapeutic properties of the compound and yet the manufacturers have burdened our literature, to say nothing of the druggist's shelves, with lactylphenetidin, citrylphenetidin, salicylphenetidin, and so on. There is no satisfactory evidence that any of these can accomplish more than the official representatives of the series or that they are less dangerous in their secondary effects.

SEDATIVES

The drugs that are used to quiet cerebral excitement may be divided into two classes, those which are used to allay nervousness and those which are employed for the purpose of promoting sleep. Under the first head are two groups of substances, the derivatives of valeryl and various compounds of bromin. The pharmacologist can recognize no effect on the system by the valerates and the clinical evidence of their value is at least questionable. Of the substitutes for the bromids, the chief advantage that is claimed is that they are less likely to give rise to gastric disturbances. The irritation of the stomach by inorganic bromids is generally due to faulty administration and it is a matter of much doubt whether there is a necessity for any of the organic combinations in which bromin is the active ingredient.

SOMNIFACIENTS

The new hypnotics have come to be almost as numerous as the coal-tar anodynes. Three of them have been sufficiently tested to merit consideration. These are veronal, bromural, and isopral. The study of the relative value of these drugs necessitates an understanding of the chemical composition of hypnotic remedies. There are three principal groups of drugs which have the power to promote sleep. These are those belonging to the methane derivatives of which paraldehyd may be taken as a type, those containing an ester of urea and those containing the ethyl-sulphone radical, of which trional is the most popular member. The introduction of a chlorin atom into the molecule of the fatty series greatly increases the narcotic power. This is illustrated, for instance, by the higher activity of chloroform as compared with ether, and of chloral as compared to paraldehyd. At the same time that it increases the narcotic powers of the drug, there is an increase of the depressant action on the circulation, so that while these halogenic compounds are potent, they are likewise dangerous. If we remember that isopral is a trichlor-alcohol of propyl its chemical alliance to chloral (trichloraldehyd of ethyl) becomes apparent. It is also physiologically very similar and although Impens (*Therap. Monatsh.*, Sept. 1903) claimed that it was a safer remedy, the elaborate investigations of Sollmann (The Journal, Aug. 8, 1908, p. 487) and of Hatcher (The Journal, June 1, 1907, p. 1849) show that while it requires smaller doses of isopral to produce sleep, it requires correspondingly smaller doses to kill. There appears, therefore, to be no reason for the introduction of this substance into practical therapeutics.

An interesting group of hypnotics which includes a number of the newer drugs are the carbamic esters, or derivatives of urea. One of these is official, the carbamate of ethyl commonly called urethan. Two drugs of this group, diethylmalonylurea (veronal) and the alphamonobrom-isovalerylurea (bromural) have been used extensively in this country. The official representative of this group, ethyl carbamate, is one of the safest of all the sleep producing drugs. Its effects, however, in comparison to chloral hydrate are relatively feeble, and while in minor degrees of insomnia it is a useful remedy, in the more obstinate types of this condition it generally fails. In the case of veronal the narcotic power of the carbamic radical has been greatly enhanced, but as is so frequently the case, at the expense of its safety. A number of unpleasant symptoms and even serious poisoning by this substance have been reported. Bromural is generally conceded to be less powerful as a somnifacient than veronal and while perhaps useful as a nerve sedative, as a somnifacient does not appear to have any advantage over ethyl carbamate (urethan).

ANALGESICS

Of the central anodynes aside from the coal-tar derivatives, there are certain derivatives of morphin which merit a word of discussion. Generally speaking, the morphin esters differ from morphin itself chiefly in the fact that they have relatively less influence upon the higher cerebral centers. They are therefore greatly inferior as somnifacients or analgesics and also less liable to give rise to narcotic habits, although not entirely free from this danger. While these remedies may perhaps have occasional value as substitutes for morphin in painful conditions, it is necessary in order to produce an even approximate degree of anodyne effect to administer relatively much larger doses than of the natural alkaloid. The chief use of this group is as sedatives to the respiratory center in the treatment of excessive cough, asthma, and other respiratory irritations. The most valuable of them for this purpose is probably the acetyl ester of morphin commonly known as heroin. The advantages of heroin are that it is less likely to give rise to narcomania, that it produces less disturbance of the general health than morphin, and that it is relatively safer. The comparative safety of a drug is not to be judged merely by the quantity required to kill, but by the ratio between the lethal dose and the effective dose. Thus, in the experiments of Impens (*Arch. d. ges. Physiol.*, 1899, lxviii, 527) it was found that if a given weight of dog was killed by 1 grain of morphin although ½ a grain of heroin would kill the same weight of animal, it required but ¼ the dose of heroin to produce the same amount of respiratory sedation as of morphin. In other words, although the heroin was twice as poisonous as morphin, it was twice as safe because the limit between the therapeutic and toxic dose was larger.

LOCAL ANESTHETICS

The introduction of the method of producing anesthesia by injection of local anesthetics into the subarachnoid space, the so-called spinal anesthesia, has stimulated chemists to the invention of a number of compounds which might possess the local anesthetic power of cocain and be free from its objectionable features. Of these local anesthetics there are four which merit consideration. These are eucain, stovain, novocain and tropacocain. The advantages claimed over cocain for each of these are that they are less toxic than cocain; they do not produce vasomotor spasm; they do not affect the pupil or accommodation; and that they may be sterilized by boiling. As the advantages of each of them over cocain are the same, it is evident that the choice between them rests on their relative powers of toxicity. Biberfeld (Quoted by Schley, *New York State Journal of Medicine*, December, 1907) compared the toxic power of cocain, stovain, and novocain, and found that if the fatal dose of cocain be taken as one, that of stovain would be three and of novocain about six. In other words, novocain was one-half as toxic as stovain and only one-sixth as poisonous as cocain. Le Brocq (*British Med. Journal*, 1909, i. 783) has made a study of the comparative value of a number of local anesthetics. As regards their toxicity he ranks them as follows: alypin, 1.25, cocain, 1.00, stovain, 0.63, tropacocain, 0.50, novocain, 0.49 and eucain, 0.41. Stovain he condemns not only on account of its comparative poisonousness but also because it is intensely locally irritant. On the basis of this last quality, local irritation, he gives the preference to novocain over eucain and all others of the group. As for the comparative power on nerve endings while Le Brocq ranked them all as about equal with cocain, except stovain which he asserts is slightly stronger, the general concensus of opinion is that eucain and novocain are distinctly, if slightly, inferior to cocain while stovain is about equal to cocain. According to Harris, a 15 per cent. solution of eucain lactate is about equivalent to a 10 per cent. solution of cocain. It is possible that the clinical inferiority of these remedies as against cocain depend on the fact that not constricting the blood vessels circulation remains active and the drug is carried away from the point at which it is applied. At any rate, it has been shown that the addition of adrenalin not only prolongs the action of these anesthetics but also enhances their power.

DIURETICS

Among the drugs which increase excretion the most interesting are the diuretics of the xanthin series. Of these, caffein is already recognized by the Pharmacopeia. The disadvantages of caffein are its effects on the central nervous system (especially on the cerebrum, producing general nervousness and wakefulness) and its action on the circulation. Owing to the effects on the vasomotor center, the dilatation of the renal blood vessels, which is so closely associated with, if not the cause of, the increased activity of the kidney, is partially antagonized by the general contraction of the blood vessels in which the vessels of the kidney more or less share. For this reason, the diuretic action of caffein is frequently not so great in practical conditions as it is in laboratory experiments on the isolated kidney. The other members of this series have a less marked action on the central nervous system and therefore are less prone to produce wakefulness and also do not contract the blood vessels by vaso-motor stimulation. Of the series, two have been largely employed, theobromin and theophyllin. Theobromin, an alkaloid found in the chocolate bean, has some, but very slight stimulating effect on the brain, and while it increases the rate of the heart, causes almost no change in blood pressure. As a diuretic it is generally held to be superior to caffein chiefly because it can be given so much more freely without danger of undue nervous excitement. Theobromin itself is insoluble in water but becomes soluble in the presence of sodium salicylate or sodium acetate. The latter combination seems less prone to upset the stomach than the combination with sodium salicylate and is probably therefore preferable. Although theophyllin occurs in small amounts in the tea leaf, the supply from this source is so insufficient that it was impractical as a remedy until a means was found to manufacture it artifically. This synthetic theophyllin occurs in the market under the trade name of theocin. The general physiologic action of this substance has not been carefully worked out but is probably similar to that of theobromin.

ARSENICALS

A great deal of interest has recently been aroused in connection with various arsenical derivatives of which an immense number have been prepared by the chemist. The last word concerning these arsenic preparations has not yet been said. A large number of active workers are at present engaged in inventing and testing new organic compounds of arsenic, especially with the idea of determining an antidote to the trypanosome of sleeping sickness and may perhaps some day reach the ideal. In 1907, Drs. Dawes and Jackson (THE JOURNAL, June 22, 1907, p. 2090) made an elaborate study of sodium cacodylate. They found that this remedy had a range of usefulness analogous to that of the inorganic forms of arsenic. The advantages of lessened toxicity as compared with arsenic is more apparent than real because the therapeutic activity of the substance is also correspondingly less. Cacodylic acid and its salts are partially broken up in the system and varying amounts of the inorganic arsenic appear in the organs of the body and in the urine. Under a variety of trade names, such as "atoxyl," and "soamin," the sodium paramidophenylarsenate has been largely used not only in those conditions in which inorganic arsenic preparations are deemed useful but also in syphilis and a number of other conditions. While there is some evidence of its value in these cases, the considerable number of instances of blindness from optic atrophy following its use (*British Med. Jour.*, March 5, 1910; abstract in THE JOURNAL, Apr. 16, 1910, p. 1323) ought to exclude it entirely from our materia medica. There is little evidence that anything can be accomplished by inorganic arsenic that cannot be done with the older forms; but the cacodylates can be given with less danger of irritating the stomach and consequently a larger amount of the metal can be introduced into the system. They are also much better preparations for hypodermic medication.

LENGTHENING THE SPAN OF LIFE

Publication within the past three years of such works as Professor Minot's "Age, Growth and Death" and Metchnikoff's "Prolongation of Life," and their quick acceptance by the general public, are marked manifestations of the interest which is being taken in working out a rationale which shall result in making old age pleasant to itself and profitable to mankind. All men desire long life, but no man desires old age if this means feebleness of mind and inability to work; and since the days of Solomon this has been the common meaning attached to length of days. It has been frequently proved, however, that useful work can be performed by the aged. Only recently Dr. W. A. N. Dorland, of Philadelphia, in a magazine article, made an end of the "forty-year limit" so wilfully misunderstood by the critics of the eminent sponsor for that unfortunate jest. Plato, Goethe, Victor Hugo, Michelangelo, Titian, Franz Hals, to mention only a few illustrious names of the past, accomplished great things for posterity at a time when most of us now living would have been making hurried plans in preparation for eternity.

The average duration of human life has been on the increase for the last three hundred and fifty years. In the seventeenth and eighteenth centuries this increase was about four years per century; in the early part of the nineteenth century it was lengthened to nine years. In Massachusetts life is now lengthening at the rate of fourteen years per century; in Europe about seventeen; and in Prussia twenty-seven. The influence of the great strides in medical science is here quite apparent; for in India, where the application of new methods of preventing and treating disease has been retarded and neglected, the average life-span is now only about twenty-five years and remains stationary.

With this advancing world movement for the ultimate conquest of disease and death, the name of Elie Metchnikoff is indissolubly associated. For more than forty years (he is now sixty-five) Professor Metchnikoff's great gifts of mind have been employed in the cause of science, and, unlike some of his less fortunate predecessors and colleagues, he has seen these gifts bring rich returns in the service of mankind. To many laymen his name was doubtless unknown until two or three years ago, when the so-called "sour-milk method" for repelling the premature onset of old age was so widely exploited in the newspapers; but this is seemingly the least of his successes, and deserves to be so regarded until time and the collection of facts shall show that the Bulgarian bacillus wages warfare against the host of would-be destroyers in the intestinal tract of every living creature, without itself exerting in turn any injurious effect on the body economy. As yet this theory remains unproved; up to the present no elixir of life has been demonstrated.

It is to preventive medicine that we must look for the maintenance of that vigorous health which shall lead to the final period when one experiences a sense of satiety of life and a wish for death. That is the ideal of ripe old age—a practical, useful life rounded to a fitting close and marked by a minimum of suffering throughout. When one sees an active intellect, abundant scholarship and splendid judgment, ripened by experience and fruitful in wise counsel, tottering to its fall because of old age, it seems more than a pity that this mental growth, cultivated at such great expense of time and effort, cannot by some strange procedure of husbandry be grafted directly into a sound young body. Someone has said of a great man rapidly approaching the period of superannuation: "He needs only a pair of strong legs to be young again." That is, of course, an unrealizable ideal. It certainly is becoming possible, however, to eliminate some of the most dreaded scourges of youth and to protect normal old age from some of its greatest dangers; and these are the functions of the progressive physician and of the true philanthropist.

THE USE OF TOBACCO

In England, at least, it seems that the question "Do you use tobacco?" must now be added to the anamnesis for women as well as for men. Angina pectoris has heretofore been comparatively rare among women; but Osler,[1] in a recent lecture, presages an increasing number of cases of cardiac neuralgia and of a mild form of angina in women, commensurate with the rapid increase of cigarette smoking among them. In England, it seems, many women are becoming habituated to the use of tobacco in this form; and possibly also, this vogue is obtaining among us to a degree which we, as practitioners, shall have to take into serious account.

Osler, for example, cites the case of an American woman whom he saw in Italy, whose daily allowance of cigarettes was never under twenty-five. Every morning precordial pains made dressing difficult for her. His observation that very heavy smokers may die from vagus-inhibition, such as obtains in angina pectoris, may be noted also in passing. Three of his acquaintances, seemingly strong, healthy men, not known to have had heart disease, but all incessant smokers of strong cigars, died suddenly and without warning—one while smoking, another while sitting comfortably in his club, the third on the beach after bathing.

---

[1] Osler, W.: Angina Pectoris, Lancet, March 12 and 26, 1910; abst. in THE JOURNAL, April 9, p. 1239, and April 23, p. 1419.

Another word may here be interjected regarding angina pectoris in our profession. The proportion of our colleagues who suffer from this malady, the pain of which is so excruciating, and so dreadful to the beholder of these sufferings, is much greater than that in other professions. One reason for this is the profound nervous shock which physicians must feel when aroused after a couple of hours' sleep—when sleep is deepest; undoubtedly, however, another reason lies in smoking, to which the profession is unusually prone. Comment has been made, flippantly, but not without truth, on the coolness with which the medical man will advise his patient against smoking, while several cigars appear most obtrusively from his vest pocket.

WHERE GLUCOSE IS NOT CORN SYRUP

One of the first breaches made in the defenses raised in the interest of the public by the passage of the national Food and Drugs Act, was that secured by the manufacturers of glucose. While the pure food law demands that the label shall tell the truth, the makers of glucose protested that they should be permitted to call their product by the more euphemistic term "corn syrup." Permission to do this was granted, though the reason for such a liberal interpretation of the law in favor of the manufacturer and so evidently against the interests of the consumer, is not known.

Fortunately for the consumer, however, some of the states are not so accommodating to special interests. The state of Wisconsin, for instance, has a pure food law which requires that the label shall contain the naked truth rather than the skilfully adorned euphemism. Moreover—and this is of even greater moment—this state has a food commissioner who believes that the law is made to protect the public rather than to be used as an advertising asset by the manufacturer.

The result of this excellent combination has been that when the glucose trust tried to sell a mixture of 90 per cent. glucose with 10 per cent. real syrup under the name "Karo Corn Syrup," two retailers were arrested and the case brought into court. The case was fought bitterly, as might be expected, but first the Circuit Court upheld the contention of the state and later the Supreme Court of Wisconsin, to which it was appealed, sustained the constitutionality of the law. The opinion expressed by Judge Stevens of the Circuit Court, regarding the question, whether the term "corn syrup" was or was not misleading is so clear-cut and full of good sense that it is worth quoting:

"The evidence convinces the court that the public generally understand a 'syrup' to be the concentrated sap of a sugar-producing plant. The term 'corn syrup' naturally suggests that the product is a syrup produced from corn. Certainly the name carries no suggestion that it is produced by the action of acid on starch, which may be made from a score of different substances as well as from corn...Even if this product be a syrup, the difference in the cost of producing it, if no other factor were involved, would make it a fraud to sell this article to the public under a name that induces the belief that it is procuring a syrup produced in the usual way by boiling down the sap of a sugar-producing plant..."

"The question is not whether the term 'corn syrup' is coming into general use; the question is whether this name deceives the public and leads it to buy that which it would not otherwise purchase. Whether the product be wholesome or unwholesome, whether the consumer have valid reasons or only unreasoning prejudices in regard to the matter, the public has a right to know, and the state the right to compel the disclosure of, what is contained in all food products offered to the consumer...When the defendants established the fact that the public generally would not purchase the product if it were put out under the name of glucose (which is shown to be a proper designation), they brought the case within the realm where the state, exercising the police power, has the right to determine that it shall no longer be sold under a name which misleads the public."

"The Constitution does not confer on any man the right to keep secret the composition of the substance which he offers to the public as a food product. To compel him to disclose its composition does not deprive him of his property without due process of law, even though it may prevent him from using a trade name. He may be compelled to sell the product for what it actually is, on its own merits, and is not entitled to the benefit of any additional market value which may be imparted to it by resorting to any means which shall make it resemble, or sell for, or in the place of, any well known food product."

And the judge of the Supreme Court voiced the same sentiment when he said: "Nor can it be said that the great mass of persons understand that 'corn syrup' is a mixture of glucose and syrup. The natural result of such use of the term 'corn syrup' is to mislead the consumers into the belief that they are obtaining a table-food of the variety and kind commonly known as syrup, the product of sugar-producing plants, and the consequences of such practice are that the consumers are misled and deceived in the respects as to the actual nature, the constituents and the value of the article as a food product."

To punish the people of the state of Wisconsin for daring to dictate to the glucose trust that this concern shall tell the truth about its product, the trust has declared a "glucose boycott" on the Badger state. No more "corn syrup" will be shipped into Wisconsin, so the papers say, "until the existing condition of affairs is reversed." This is a modification of the famous "red clause" of the "patent medicine" interests, adapted to the glucose industry. For the past few years "Karo"—a trade-marked name for glucose flavored with syrup—has been heavily advertised all over the country. We may now expect the advertising patronage of the glucose trust to be withdrawn from the state of Wisconsin in the hope that the newspapers of the state will bring pressure to bear on the state legislators to amend and emasculate the present law. It is to be hoped that Wisconsin newspapers in this instance will not sell their birthright of journalistic freedom for a paltry mess of advertising pottage, as they did when a bill was before their legislature requiring "patent medicine" manufacturers to state the composition of their nostrums.

As for the people of Wisconsin, they are doubly to be congratulated: first, on possessing both an admirable law and honest officers to enforce it; second, on being relieved of the necessity of watching to see whether they are having a glucose mixture foisted on them in the place of, and at the price of, real syrup. Incidentally Wisconsin would seem to offer great commercial opportunities to the makers of real syrup.

PHARMACEUTICAL MANUFACTURERS AND THE GREAT AMERICAN FRAUD

The story is told that a few years ago an enterprising gentleman of the Rufus Wallingford type advertised that he would mail, post paid, to all who sent him fifty cents, a handsome picture of the Father of Our Country. Those who rose to the bait received an uncancelled two-cent postage stamp. The advertiser was declared a fraud and the get-rich-quick scheme was frustrated.

Let it be supposed for an instant that the courts had decided in this case that no technical offense against the law had been committed; that as the advertiser had actually furnished what he advertised he was legally within his rights. Let it be supposed, further, that under such a court ruling the postal authorities contracted to furnish this "picture" seller all the "pictures" (stamps) that he cared to purchase. What would be the status of the government in such a case? Undoubtedly in the eyes of the public the postal authorities would have been considered as aiding and abetting a swindle and a fraud—a moral fraud, and one more despicable than a legal fraud because under the existing law it could be perpetrated with impunity.

Supposedly reputable pharmaceutical houses that furnish medicinal products to firms or individuals whom they know to be in the business of cruelly defrauding that most helpless portion of the public—the sick—are in the same position that the postal authorities would be in the hypothetical case just given. Legally they may be within their rights but ethically and morally their course is iniquitous. No amount of argumentative sophistry will justify, in the eyes of the medical profession, the attitude taken by those manufacturing pharmacists who are willing to sell their products to any who will pay for them, no matter to what use the drugs are to be put.

In our Pharmacology department, this week, attention is called to specific cases in which nostrum exploiters have been supplied with their stock-in-trade by pharmaceutical houses which should be above such things. That a much greater list than that given could be made if the data were available, nobody doubts. "Castor-Oil Pills" were widely exploited not long ago by an advertising man; the pills, which were a simple laxative mixture without a trace of castor oil, are said to have been made by one of the large "ethical" pharmaceutical firms which must have known of the dishonesty and fraud connected with their sale. "Pennyroyal Pills," which were extensively advertised as alleged abortifacients but which contain no pennyroyal, are also credited as having their origin in a pharmaceutical house which stands high in the estimation of the medical profession. One of the cruellest and most fraudulent of the innumerable "consumption cures" on the market is alleged to be put up for the quack who sells it by an "ethical" firm. And so it goes.

How much longer manufacturers of pharmaceuticals will maintain this Janus-faced attitude depends largely on the medical profession. It is safe to assert that no firm would for long continue this wretched business in the face of insistent disapproval from physicians.

Current Comment

CHINA AND OPIUM

According to missionary testimony, China is acting in earnest in the suppression of the opium curse, and anti-opium leagues have been formed in many of the great cities. According to Rev. W. L. Beard, there were, in the city of Fu Chau, three years ago, more opium dens than rice shops, but now, through the influence of the anti-opium league, there is not a single one. One of the most encouraging evidences, however, is the fact stated in a recent dispatch that the danger of famine in the western districts of China is lessened by the amount of land which has been diverted from opium culture under the recent laws and devoted to the growth of food products. While there used to be enormous fields of poppy flowers, making this crop the most conspicuous of any, there are now fields of rice and hemp and the open culture of the opium plant is largely a thing of the past. Without doubt there are opium dens publicly open in some provinces, especially near the European settlements, and illicit sales still continue in Chinese "blind pigs" elsewhere, but the outlook seems to be encouraging.

FACULTY CHANGES

Dr. David Streett, dean of the Baltimore Medical College, writes that the following additions have been made to the medical faculty: Dr. T. B. Marden has been elected professor of biology, including histology, embryology and zoology; Dr. E. L. Whitney has been reelected professor of physiologic chemistry and pharmacology; Dr. H. Raymond Spencer, demonstrator in physiology; Dr. Reginald D. West, demonstrator in anatomy. It is stated that these instructors will devote all their time to teaching and research and that a full-time instructor in pathology and bacteriology will also be secured in the near future.

NEW INSTITUTE OF CLINICAL RESEARCH

It is reported that $200,000 has been donated by Mrs. Robert Dawson Evans, of Boston, for the erection of an Institute of Clinical Research and Preventive Medicine, to be under the direction of the Massachusetts Homeopathic Hospital. It will be built on land immediately adjoining the Boston University School of Medicine with which it will be connected by a passageway. It will also be connected by a subway with the hospital. The object of the institute is the investigation of all phases of clinical medicine as they are allied to methods of laboratory study, including particularly cancer and other diseases at present considered incurable. There will also be a ward for neurologic patients and the top floor will be entirely occupied by laboratories of pathology, bacteriology, physiology, chemistry and drug pathogenesis.

STRAW ITCH

Straw itch may be considered a new disease or, possibly more properly, a disease of which we have but recently acquired definite knowledge. In the early part of the summer of 1909 there was an outbreak of an eruptive skin disease among sailors in Philadelphia. The disease was studied by Goldberger and Schamberg, who ascertained that the cause was a small mite (*Pediculoides ventricosus*) in the straw of mattresses on which all those affected with the disease had either slept or had put their clothes. Outbreaks of what is in all probability the same disease have been reported from various points in New Jersey, Maryland, Pennsylvania, Ohio and Indiana. The mite preys on the larvæ of certain insects which live on grain and especially wheat. It remains on the straw and may attack man during the handling of the grain as in thrashing or if the straw is used in filling mattresses those sleeping on them may be infected. The main symptoms of the disease are a severe itching and an eruption consisting of wheals surmounted by vesicles which develop in a few hours into pustules.

Medical News

CALIFORNIA

College Commencement.—On June 2 the Oakland College of Medicine and Surgery graduated three physicians. Dr. F. Dudley Tait, San Francisco, delivered the principal address.

King Edward's Physician in San Francisco.—Sir Felix Semon, K.C.V.O., and wife, physician extraordinary to the late King Edward VII, made a short stay in San Francisco, May 27, on the completion of a tour around the world to the eastward.

Antituberculosis Societies.—The San Diego Society for the Study and Prevention of Tuberculosis was recently incorporated. Among the physicians taking an active interest are Drs. Joseph A. Parks and Fred R. Burnham.——The Long Beach League for the Prevention of Tuberculosis has elected Dr. Charles Bown, president; Dr. Francis L. Rogers, secretary, and Dr. Balzar W. Scheurer, treasurer.

Personal.—Dr. William K. Lindsay, a physician of Sacramento, has been appointed by the State Board of Education to supervise the health department work in the public schools. Dr. Gustav Henrikson has been made assistant.——Dr. and Mrs. Harry E. Alderson, San Francisco, have gone to Honolulu.——Dr. Augustus F. Shafer, Bakersfield, has been employed by the Mexican government to combat typhus fever.——Dr. Stewart M. Doherty, Napa, has been appointed pension examining surgeon.——Drs. Robert F. Rooney and J. N. Ward have been appointed on the board of health of Auburn.

COLORADO

Hospital for State Penitentiary.—The former Women's Department of the State Penitentiary, Canon City, has been remodeled into a hospital building with sun parlor and seperate quarters for tubercular patients.

Inspection of Lying-in Hospitals.—The State Board of Charities recently conducted a rigid inquiry into the methods of lying-in hospitals in the state. Insanitary and otherwise objectionable institutions have been closed. The state will safeguard infants adopted from such institutions.

ILLINOIS

Chicago

Personal.—Dr. and Mrs. Albert E. Mowry sailed from Montreal, June 30, for the Continent.——Dr. Benjamin H. Frayser has also left for Europe.——Dr. and Mrs. William O. Krohn have left for Europe by way of a motor trip through New England to Montreal.

Chicago Medical Society Election.—The annual election of the Chicago Medical Society occurred June 14 and resulted as follows: President, Dr. Alexander Hugh Ferguson; secretary, Dr. George F. Suker; councilors at large, Drs. Henry F. Lewis, Arthur M. Corwin, Adolph Gehrmann, Charles J. Whalen and Ludwig Hektoen.

Police Department to Run Hospital.—The Harrison Street Emergency Hospital will be conducted under the supervision of the chief of police after July 7, when it will be abandoned by the city health department. Chief Steward says it is the only hospital of the kind in the city and too valuable to be abandoned. It cares for from thirty to fifty cases each week. The chief inspected the hospital and found it in good condition.

The Work of the United Charities.—The report of the work accomplished during the past year by the United Charities of Chicago is sufficient to justify the hope that $50,000 additional annual subscriptions may be secured, making in all $200,000 annual income. There was a deficit of $2,300 in the last year's work, which is considered a good showing. Infant mortality has been reduced to 165 in each 100,000 inhabitants, the lowest record reached in Chicago.

Donations for Loyola Medical Department.—It is reported that $60,000 has recently been contributed for the construction of a new three-story medical building, at the corner of Fulton and Ada streets, for Loyola University Medical Department. This is to provide space for anatomic and chemical laboratories and for two large lecture rooms. It is also reported that provision has been made for five instructors who will devote all their time to teaching in the medical school.

IOWA

Drake Alumni Meeting.—At the alumni meeting of Drake University, held at Fort Madison recently, Dr. John R. Walker, Fort Madison, was elected president. A gift of $50,000 to Drake University by Theodore P. Shonts, an alumnus, now of New York, was announced.

Personal.—Dr. Harry E. Kirschner, superintendent of the state sanatorium at Lakedale, has been granted a three months' leave of absence for study in the east. Dr. Clarence E. Van Epps, Iowa City, will have charge of the sanatorium during Dr. Kirschner's absence.——Dr. Irenarch S. Buzard, Russell, has gone to England for study.——Dr. William P. Crumbacher, superintendent of the state hospital for insane, Independence, has been reappointed.——Dr. Francis H. Boucher has been appointed coroner to fill the unexpired term of the late Elijah W. Jay, at Marshalltown.

MARYLAND

Psychiatric Society Meets.—The Maryland Psychiatric Society was entertained at Creighton's Sanatorium, Lutherville, June 23, by Dr. L. Gibbons Smart. A paper was read by Mr. Nathaniel G. Grasty, secretary to the supervisors of city charities, on "The After-Care of the Insane." A committee was appointed to report on an epileptic colony in Maryland. The next meeting will be held in Annapolis.

Baltimore

New Feature of Hopkins Medical Clinic.—A "heart station" will be instituted at the medical clinic of Johns Hopkins Hospital next fall. It will be equipped with a special laboratory for examining the heart by electricity and other new graphic methods of registration.

Law Cases.—Suit for $50 against Dr. John D. Blake for alleged unskilled treatment of a child at birth, was decided in his favor.——A verdict for $500 is said to have been awarded May 25, against Dr. G. Milton Linthicum on account of injuries sustained by a driver from a mule frightened by Dr. Linthicum's automobile.

Personal.—Dr. Alexius W. McGlannan, of the College of Physicians and Surgeons, delivered the address at the commencement of St. Joseph's College, R. C., June 21.——Dr. John M. T. Finney sailed for Europe June 22.——Dr. Peregrine Wroth, Hagerstown, was operated on at the Union Protestant Infirmary, June 22, for appendicitis.——Surgeon Henry R. Carter, United States Public Health and Marine-Hospital Service, was given the degree of LL.D. by the University of Maryland at its recent convocation.

MISSOURI

St. Louis

Hospital Staff Named.—The hospital board of St. Louis has appointed thirty-six physicians on the visiting staff of the several institutions for four months. Future appointments will be determined by competitive examination.

Medical Degrees at Washington University.—Washington University graduated 175 students in Graham Memorial Chapel June 8. Rev. Dr. George Hamilton Combs, Kansas City, delivered the main address. Dr. William H. Welch also addressed the students.

American Medical College Reorganized.—The trustees of the American Medical College of St. Louis—eclectic—decided, June 6, that in the future the college should be conducted as a regular college of medicine. New officers elected were: Dr. James Moores Ball, dean; Dr. Ward T. Burdick, secretary, and Dr. J. Joseph Link, treasurer.

Hospitals Merge.—The Martha Parsons Free Hospital for Children and the St. Louis Children's Hospital consolidated June 1. The Martha Parsons property will be abandoned and the patients transferred to the St. Louis Children's Hospital. The income of the former will be used jointly with that of the latter for maintenance of the institution.

Apportions Medical Fund.—The income from the $100,000 originally intended for the purchase of a suitable hospital site, and estimated at $5,000 annually, is planned to be apportioned among the hospitals connected with the St. Louis University, as follows: St. John's, $1,000; St. Mary's, $500; Alexian Brothers', $300; St. Anne's Infant Asylum, $200, and Rebekah Hospital, $3,000.

NEW YORK

Employers Liability Bill Signed.—Among the last bills signed by Governor Hughes was the Wainwright compulsory employers liability bill. A plan of compulsory compensation applicable to certain dangerous employments was presented in the present bill and it also contained the proposals of the commission appointed to investigate the subject of employers liabilities as amended in certain particulars by the legislature.

Milk Violations Decrease.—Figures compiled at the attorney-general's office at Albany indicate that the strict enforcement of the pure food law since Jan. 1, 1909, has raised the standard of milk sold throughout the state. In the last few months the number of violations in regard to the sale of milk has shown a decrease. For several years impure milk has given the attorney-general's office more trouble than any other article of food.

Mayors' Health Conference.—The Mayors' Health Conference which convened in Schnectady June 24, will become a permanent institution and will hold conferences annually. At this session Dr. Albert W. Ferris, President of the State Commission in Lunacy, read a paper on "Fighting Insanity." Prof. Walter Wilcox of Cornell University spoke on "Methods of Determining Economic Losses from Preventable Diseases." He placed the economic loss of the nation due to tuberculosis at from $450,000,000 to $650,000,000 annually. Dr. H. D. Pease of the Lederle Laboratory places the loss in New York state at $70,000,000 annually. Dr. George W. Goler of Rochester spoke on "How to Get Competent Health Officers." At the evening session Dr. Woods Hutchinson spoke on "The Greatest Problem of Modern Sanitation," Dr. Harvey W. Wiley of Washington on "What the Small City Can Do to Protect Its Food Supply," and Prof. Charles Zueblin of Boston on "Obligations and Opportunities of Local Officials."

New York City

Seagoers.—Dr. and Mrs. W. E. Lambert, Dr. and Mrs. J. William White, Dr. R. M. Cramer and Dr. Austin W. Hollis have sailed for Europe.

Gift for Cancer Victims.—The Servants of Relief, under the leadership of Mother Alphonse, Nathaniel Hawthorne's daughter, have received a gift of $25,000, with which they expect to build an annex to the cancer hospital, known as St. Rose's Home, on Cherry street.

Dispensary Reopened.—The Bedford Dispensary, Atlantic and Ralph avenues, has been reopened after having been closed for a period of two years on account of lack of funds. A band of women who have made it possible to renew this work are determined that treatment shall be reserved for those who really are needy and have appointed several agents who look up applicants.

More Aids at Bellevue.—The Board of Trustees of Bellevue and the allied hospitals made three new medical appointments. In accordance with the request of Dr. W. H. Smith, the general medical superintendent, Drs. George O. Hanlon and Mark L. Flemming were appointed assistant medical superintendents and Dr. Edward S. Bishop was appointed resident physician in charge of the alcoholic service.

Personal.—The degree of doctor of science was conferred on Dr. Francis Valk at the commencement exercises of Washington College at Chestertown, Md., June 15.——The following changes have taken place in the Eastern District Hospital, Brooklyn: Dr. Martin J. Leibovici has completed his service and opened offices for practice; Dr. Aaron B. Cohn has been promoted to house surgeon; Dr. Louis J. Frank has been appointed ambulance surgeon; Dr. Joseph Rosenberg, house physician, and Dr. Albert Polon, pathologist.

Objects to Judicial Decision.—Bellevue Hospital will cause an appeal to be prosecuted in a case recently decided in the supreme court in this city by Justic Erlanger. A lawyer was charged with violating the penal code in having procured an attendant in Bellevue Hospital to furnish him with information regarding the condition of patients being treated for personal injuries attributed to negligence. The defendant contended that it was no crime to solicit such information and Justice Erlanger seems to have upheld this view.

Find Evils in Hospitals.—A special commission appointed by the State Board of Charities has just completed an investigation of some sixty private hospitals in the greater city and adopted resolutions to remedy some of the evils found. In at least twelve of the hospitals the sanitary, ventilating and fire-escape facilities were found to be inadequate. A half a dozen hospitals were found to be much overcrowded, there being insufficient space between the beds. One of the resolutions provides that no patient shall be retained at public expense in any hospital wholly or partly under private control, unless the building is fireproof and sanitary with at least twelve hundred cubic feet of air space for each patient in the ward.

New Long Island Hospitals.—The hospital being erected on Surf avenue, Coney Island, by the Brooklyn Children's Aid Society at a cost of $90,000, will be managed in connection with the Seaside Home. It is expected that it will be ready by December 1.——St. Mary's Maternity Hospital, Brooklyn, will be reopened after having been closed for a year. It has been remodeled and renovated at a cost of $50,000 and will be *known hereafter as the Hospital of the Holy Family.*——Those interested in the proposed Beth Jacob Hospital and Dispensary announce that sufficient funds have been raised to enable them to begin erection. The hospital is to be conducted in accordance with Jewish dietary laws, though they will not discriminate in accepting patients.——The Bayside Infirmary, a twenty-bed, well equipped private hospital, under the directorship of Dr. Harris A. Houghton, will be opened for patients at Bayside, August 1.

PENNSYLVANIA

Personal.—Dr. Henry H. Daney, Phoenixville, while hastening to the bedside of a dying friend, June 24, was thrown from an automobile and seriously injured.——Dr. William W. Keen, Philadelphia, sails for England July 2.——Dr. William T. Moore, Washington, has been appointed medical missionary to Egypt by the board of foreign missions of the Presbyterian Church.

Smallpox at Dickson City.—An epidemic of smallpox has been discovered at Dickson City, which is practically a suburb of Scranton. Twenty-six cases have been reported. Dr. Samuel Dixon, head of State Department of Health, has assigned Dr. P. F. Royer to take charge of the situation. All patients convalescing and those suspected of being infected are strictly quarantined.

King Edward Memorial Research Laboratory.—This laboratory is not to be given to the proposed municipal tuberculosis hospital, as stated in THE JOURNAL June 18, but is given to the hospital of the Tuberculosis League of Pittsburg, which has been carrying on a comprehensive municipal scheme for the city of Pittsburg for the past three years. Dr. William Charles White, the director of the tuberculosis league, is to be the director of the new laboratory.

Medical Societies Celebrate.—A joint midsummer outing, closing the winter session of the Lackawanna and Luzerne county medical societies, was held on June 21 at Rocky Glen Park, near Scranton. One hundred and eighteen physicians attended the afternoon session, at which addresses were made and papers were read. In the evening a banquet was served in the "Swiss Chalet" of the park. Dr. J. M. Wainwright is president of the Lackawanna and Dr. G. A. Clarke is president of the Luzerne County Medical Society.

Governor Talks to Medical Alumni.—At a meeting of the alumni of the Medico-Chirurgical College, June 2, Governor Stuart was the chief speaker. He declared that Pennsylvania had expended more money in the advancement of medical science than any other state. He said that Pennsylvania gives $7,000,000 to the cause of medicine and $1,000,000 goes annually to the support of the health department. Pennsylvania is a pioneer in the cause of tuberculosis and has expended $2,000,000 in two years in the erection of sanatoriums for the care of persons afflicted with the disease.——In discussing the question of union of the Medico-Chirurgical with Jefferson, Henry F. Walton, president of the board of trustees of the Medico-Chirurgical College, expressed himself as unalterably opposed to such a union.

Henry Phipps Tuberculosis Institute.—Mr. Henry Phipps of New York has selected the University of Pennsylvania to carry on the work of the Phipps Institute and has acquired ground in Philadelphia on which will be erected a hospital for this purpose. The extent of the benefaction exceeds $5,000,000. The report of the comittee appointed to consider the future policy of the institute has been approved by Mr. Phipps and the trustees of the university. For director of the laboratory Dr. Paul Lewis, now of the Rockefeller Institute, has been selected; for director of the sociologic department, Mr. Alexander M. Wilson, of the Boston Association for the Relief and Control of Tuberculosis; for director of the clinical department, Dr. H. R. M. Landis. In addition to a board of eight directors, who will be directly responsible to the trustees of the university, an advisory council will meet annually at the institute. The following have accepted the invitation to serve as members of this body: Drs. Samuel G. Dixon, Harrisburg, Pa.; S. M. Lindsay, New York City; William H. Baldwin, Washington, D. C.; Herman M. Biggs, New York City; William H. Welch, Baltimore; Theobald Smith, Boston; H. Gideon Wells, Chicago; Simon Flexner, New York City; James A. Miller, New York City; L. Brown, Saranac, N. Y.; Henry Baird Favill, Chicago, and James Pratt, Boston.

Philadelphia

Addition to Methodist Hospital.—Through the munificence of Thomas Bradley, president of the Methodist Hospital, a four story building, known as Bradley Hall, will be built at once on the hospital grounds at Broad and Wolf streets. The building will cost $41,000 and will contain kitchens, dining rooms, sewing room, chief resident's suite and rooms for help, thus affording room in the main building for fifty additional beds.

Personal.—Dr. Walter S. Cornell, demonstrator of osteology at the University of Pennsylvania, was taken to the university hospital on June 20, suffering from gastric ulcer. His condition is improving.

Plan Home for Feeble-Minded.—At a meeting held at the Civic Club on June 21, attended by prominent sociologists and city officials, plans were considered for the establishment of a fully equipped institution for the care of feeble-minded children. From statistics gathered by Director Neff of the Bureau of Health it was estimated that there are 1,000 feeble-minded persons at large in this city, through the lack of sufficient accommodations in the state institutions. Byberry, where the city owns vast tracts of land, was favored as the site for the erection of such home.

Pellagra at Blockley.—Dr. W. W. Hawke, chief resident physician of the insane department of the Philadelphia General Hospital, under the supervision of government officials, began a rigorous examination of all the patients in the insane department. Twelve cases of pellagra have recently been discovered in the institution, the first cases of the disease recognized in this city. Sixteen other patients are believed to be pellagra victims, but the diagnosis has not been fully established. Dr. J. D. Long, a government physician, who has made an extensive study of pellagra, and Dr. H. F. Harris, of the Georgia State Board of Health, in association with Dr. Hawke, are making a careful study of the cases.

GENERAL NEWS

Milk Commissions Meet.—The American Association of Medical Milk Commissions held its fourth annual session in St. Louis, June 4 and 6, and elected the following officers: President, Dr. Milton J. Rosenau, Harvard University; secretary, Dr. Otto P. Geier, Cincinnati; treasurer, Dr. Albert W. Myers, Milwaukee, and councilor, Surgeon John W. Kerr, U. S. P. H. and M.-H. Service. Philadelphia was selected as the meeting place for 1911.

Memorial to Dr. Howard T. Ricketts.—A memorial tablet was unveiled in the City of Mexico in honor of Dr. Ricketts, June 24, as will be seen by the invitation to the ceremony *given below:*

> "La Secretaría de Instrucción Pública y Bellas Artes suplica á Ud. se sirva honrar con su presencia la ceremonia que se efectuará el 24 del actual, á las 10 de la mañana, en el Instituto Bacteriológico Nacional (Popotla, D. F., calle de Gonzalo Sandoval, 4), para descubrir una lápida conmemorativa en el laboratorio del mismo Instituto en que trabajó el Sr. Dr. D. Howard T. Ricketts, distinguido profesor de las Universidades de Chicago y Pennsylvania, que perdió la vida en el curso de sus investigaciones sobre el tabardillo. *México, 17 de junio de 1910.*"

[The Minister of Public Instruction and Fine Arts requests the honor of your presence at the ceremony which will be held at 10 a. m., June 24, in the National Institute for Bacteriology, for the unveiling of a memorial tablet in the laboratory of that institute in which worked Senor Dr. Don Howard T. Ricketts, distinguished professor in the universities of Chicago and Pennsylvania, who lost his life in the course of his research on Mexican typhus. Mexico, June 17, 1910.]

American Association of Medical Journal Advertisers.—This association held its fourth annual meeting in St. Louis, June 9. Vice-President Dr. S. Grover Burnett, Kansas City, presided. The secretary's report showed that a large number of objectionable advertisements had been eliminated from the pages of medical journals through the efforts of the association during the year, but that there was much yet to be done to clear their pages of quack advertisements. The following resolution offered by Dr. Burnett was unanimously adopted:

> *Resolved*, That, where the business of an institution has been built up by newspaper advertising or other irregular methods, the owners or managers thereof shall not be accepted as members of this association or their advertisements permitted to appear or remain in journals containing the advertisements of members of this association until such institution has purged itself of irregularity to the satisfaction of the county medical society of the county in which it is located.

The following officers were elected: President, Dr. S. Grover Burnett, Kansas City, Mo.; vice-president, Dr. George H. Moody, San Antonio, Tex.; secretary, Dr. George E. Pettey, Memphis, Tenn.; executive committeemen, Dr. J. Joseph Kindred, Astoria, L. I.; Dr. F. H. Barnes, Stamford, Conn.

CANADA

Annual Meeting of the Canadian Association for the Prevention of Tuberculosis.—The seventh annual meeting of this association was held in Montreal, June 7 and 8, under the presidency of Prof. J. George Adami. Dr. Adami advocated the formation of Protestant institutions for the care of the tuberculous similar to those in vogue under the charge of the Catholic Sisters of Quebec, who the past few years, especially the Sisters of Providence, have been doing a great deal of good work along these lines. Major-General George M. Sternberg of Washington delivered an address on "The Housing of the Working Classes As a Factor in the Prevention of Tuberculosis."

Personal.—The following Toronto practitioners are sailing for Europe: Drs. Adam H. Wright, Herbert A. Bruce, Allen Baines, Irving H. Cameron, F. N. G. Starr.——Dr. Charles A. Hodgetts, secretary of the Ontario Board of Health, has resigned and has been appointed secretary to the public health section of the Canadian National Conservation Commission. Dr. J. W. McCullough of Alliston, Ont., has been appointed to succeed Dr. Hodgett.——Dr. A. I. Maider, Halifax, has returned from Edinburgh.——Dr. Oskar C. Gruner, clinical pathologist to the General Infirmary, Leeds, England, has been appointed pathologist to the Royal Victoria Hospital, Montreal, and lecturer on pathology at McGill.——Dr. Charles Sheard, medical health officer and chief of the street cleaning department of Toronto, has resigned.——Dr. John D. Wilson, London, is reported to be critically ill.

The Carnegie Foundation Report and Canadian Medical Colleges.—According to this report, which has just been distributed in Canada, four of the eight medical colleges would meet the needs of medical education in Canada. These are Toronto, McGill, Manitoba and Laval at Quebec. Toronto and McGill are put down as first class. Toronto has about reached its efficiency. McGill and Manitoba are capable of considerable expansion. Laval at Montreal and the Halifax Medical College are feeble. London is said to be very bad. The future of Queen's at Kingston is doubtful. Probably it would be a good thing for Canadian medical education if Laval at Montreal united with Laval at Quebec, that Halifax should become a preparatory school for McGill, and the Western at London and Queen's should become preparatory schools for Toronto. McMaster University, Toronto, however, has some idea of some day establishing a medical faculty. Later on, as the west develops, there will likely be a medical college in Vancouver.

Convocation at McGill.—On June 10 convocation was held at McGill University for medical and dental degrees. Dr. T. Wesley Mills, who for many years has been professor of physiology, delivered an address to the graduates in which he announced his retirement. Dr. Mills will take up his residence in Germany for the recuperation of his health. In his address he scored the citizens of Montreal for taking so little interest in their university. Referring to the teaching of medical students, he said they were given a great deal too much to digest; they should be taught less but taught better. He thought there were too many practitioners on the faculty, and that the aim of the faculty should be to teach the students to be men first and medical practitioners second. At the close of his address he was presented with a purse of gold by Dean Shepherd, on behalf of the faculty. Dr. Shepherd announced the retirement of Prof. William Gardner from the chair of gynecology. Dr. Gardner has been connected with the faculty for twenty-seven years. Announcement was also made of the appointment of Dr. J. C. Simpson as professor of embryology and histology.

LONDON LETTER

(From Our Regular Correspondent)

LONDON, June 18, 1910.

The Antituberculosis Campaign

The antituberculosis campaign is still being pursued with great energy, but the problem of providing adequate sanatorium accommodation remains a difficult one. There has been a great diminution in the number of cases of consumption in England and Wales in recent years, but they still amount to between 250,000 and 300,000, while the number of beds available at sanatoriums numbers only 1,500. The average duration of treatment in a sanatorium is from 4 to 6 months. Therefore there is only sanatorium accommodation for 1 to 1.5 per cent. of those who may require it. Each year there are 40,000 deaths from consumption and 20,000 from other forms of tuberculosis. It seems that adequate accommodation can be provided only by the state or by some form of insurance against disease, including tuberculosis, like that adopted by Germany. The cost would to a large extent be saved by diminution in the loss which now results from tuberculosis. It is calculated that friendly societies pay each year for consumption $6,000,000, the poor-law authorities $7,000,000 and the special hospitals $2,500,000. In addition to this the indirect loss due to loss of wages cannot be less than $20,000,000 to $25,000,000. This makes a total annual loss of $40,000,000, a figure which some authorities consider much too low. Addressing the Manchester and Salford Sanitary Association, Dr. Arthur Latham of St. George's Hospital said that if all this money were intelligently spent the disease could be eliminated in 20 to 30 years.

The National Association for the Prevention of Consumption and Other Forms of Tuberculosis is undertaking a new educational campaign by means of traveling tuberculosis exhibitions, caravans with lantern-slides, popular lectures, an information bureau for the press and public and the distribution of leaflets. It is estimated that an efficient campaign on these lines will cost not less than $25,000 annually. A special effort is being made to secure the cooperation of working-class organizations in the campaign. A tuberculosis exhibition has been held at various centers in London. At Whitechapel (in the east end) 70,000 persons visited it, and it was equally successful at the other centers, as well as in the country, at Cambridge, Oxford and other places.

Decline of Venereal Disease in the Army in India

One of the remarkable features of the medical statistics of the British army in recent years is a decline in the number of cases of venereal disease. In India the admission rate in 1908 fell to 69.6 per 1,000, the lowest on record. This result is largely due to the efforts of the authorities to stamp out vice and to make the men's lives attractive. The various church bodies and the Royal Army Temperance Association have worked strenuously for this end.

Leprosy in London

The presence of a case of leprosy in the Whitechapel Union Infirmary (in the east end of London) has given rise to some anxiety, as no provision exists in London for the isolation of this disease, which in the popular mind is regarded as an almost extinct rarity in this country. But the fact is that London always contains a sprinkling of lepers who go about their daily work without doing harm to anyone and without their neighbors being aware of the fact. Some of them are clerks working in city offices; others perform a certain amount of manual labor, and several leper children regularly attend the London county council schools. According to Sir Jonathan Hutchinson there are never fewer than 100 cases of leprosy in England and now there are probably 50 in London. The presence of the disease is always concealed by the patients and their physicians do not reveal it because of the popular prejudice against the disease. It always occurs in persons who have been abroad and lived in leprous districts. No case of contagion in England is known. Sir Jonathan Hutchinson, who has always taught that the leprosy is not contagious, has had under his care for the last 10 years a boy suffering from the disease. The lad is now nearly 20 and has recovered. He went to school in London and is now working in an office.

PARIS LETTER

(From Our Regular Correspondent)

PARIS, June 17, 1910.

Protest Against the Disorders in the Concours

The council of the Lyons medical college, the Société des médecins des hôpitaux de Paris, and the Syndicat médical de Paris, like the professors of the Paris college of medicine, have voted their disapproval of the disorders which took place at the last concours de l'agrégation. The syndicate has resolved that the question of the reform of medical instruction ought to be seriously studied by the minister of public instruction and ought to be solved as soon as possible by a commission comprised of equal numbers of professors and of practicing physicians.

Dedication of Pasteur Monument at the Higher Normal School

When the Pasteur monument in Paris was erected a few years ago by public subscription, the cost of the monument did not entirely absorb the funds. At the suggestion of Dr. Roux and the family of Pasteur this remainder was offered to the Ecole Normale Supérieure for a modest memorial to the great scientist in the school rendered illustrious by his own works. After having taught in the scientific schools of Strasburg and of Lille, in 1867 Pasteur entered the Paris normal school as director of scientific studies, and remained there until he established the Pasteur Institute in 1889. Most of Pasteur's great discoveries issued from the modest laboratory of the normal school on the rue d'Ulm, near which the monument stands. The dedication took place on June 5.

Return of the Charcot Mission

The mission for the study and exploration of the Antarctic regions directed by Dr. Jean Charcot, son of the celebrated neurologist, has just returned to France. The program laid out for the expedition by the Académie des Sciences included exploration of that region of the Southern Pacific included between the meridians of South America and New Zealand and the study of meteorology, terrestrial magnetism, marine currents and natural history of this unknown region.

BERLIN LETTER

(*From Our Regular Correspondent*)

Berlin, June 9, 1910.

The Death of Robert Koch

The wave of excitement set in motion by the death of our gifted bacteriologist and hygienist has not yet subsided. In consequence of the importance of this pioneer investigator, medical societies as well as the press and society in general are still engrossed with this most significant event of the last week. The ashes of the dead scientist, cremated in Baden-Baden, have been brought to the Institute for Infectious Diseases, which was the place of his labors for the last decade, and they will be permanently installed in a room which, with the permission of the national authorities, is to be converted into a mausoleum for Koch. In this room also there will be placed the bust, contributed by his pupils on his sixtieth birthday, his works and other memorials. A memorial room will be produced, similar to the one which has been provided for Pasteur in his Paris institute. In order to avoid a large number of single memorial services in the various societies of which Koch was an honorary member, a committee has been formed which is preparing a single memorial service for all these bodies in common. The date for this celebration has been postponed to December 11 of this year, which will be the sixty-seventh birthday of Robert Koch; this resolution has been taken because, as is generally understood, in the next few weeks many of the persons who would be interested in this memorial will be away from home and, moreover, because representatives from foreign countries are expected at the celebration (particularly from America, an expectation which we hope will not be disappointed), and finally because Koch himself wished a quiet interment. The memorial address at the proposed service will be delivered by Gaffky, the oldest pupil of Koch and his successor in the directorship of the Institute for Infectious Diseases. Gaffky is also chairman of the committee, which includes in addition a large number of prominent Berlin physicians.

Mortality in Prussia in 1908

In 1908 362,259 males and 331,465 females died in Prussia. In addition there were reported 21,876 still births of the male sex and 16,908 of the female. Without reference to the still births the mortality rate per thousand on Jan. 1, 1908, was 18 (for males, 19.1; for females, 17). This figure is the most satisfactory since the institution of uniform vital statistics (quite as good as the two preceding years).

Warning Against Selecting the Medical Profession

The Leipsic league has lately again undertaken to dissuade the graduates of our secondary schools from undertaking the study of medicine. In the circular issued for this purpose it is noted that in 1908 only 618 places could be placed at the disposal of 898 physicians who were seeking localities to practice through the intermediation of the league. In that year only 6,000 persons were studying medicine, but the number of students of medicine has risen continually since 1905, from 6,080 in 1906 to 8,568 in 1908-09, and in the summer semester of 1909 to 9,509. That the income of German physicians is quite small has been recently shown by a statement of the statistical bureau of Saxony. According to this, in the entire kingdom of Saxony 34.8 per cent. of the physicians had not yet an annual income of $1,050 (4,300 marks), and only 44.8 per cent. of the physicians received more than $1,500 (6,300 marks). In this calculation of the income the professional expenses have been deducted, but on the other hand the income from private property of man and wife and all other outside sources are included. These economic conditions will become even worse after the introduction of the new imperial insurance law, for then all persons who have an income of $500 (2,000 marks) and under will be entitled to sick insurance. This means that in Prussia, for instance, 92 per cent. of the population will belong to the Krankenkassen.

Lactation in the Blazek United Twins

Considerable scientific interest has been aroused over the phenomena of lactation in the united Bohemian twins, the Blazek sisters, one of whom was delivered recently of a boy at Prague (mentioned in the Vienna letter April 28). The father of the child is the manager of the two sisters, who has exhibited them to the public for several years. The Blazek twins form a pygopagus; that is, twins joined at the buttocks: all the organs of the trunk are duplicated, except that the rectum and the introitus vaginæ are in common. Formerly the sisters menstruated for a four to five day period. During pregnancy the menses ceased in the pregnant woman, while the other sister menstruated regularly until the last two months before the birth. It is remarkable that lactation set in not only in the woman who was delivered but also in her sister. Dr. Basch, who examined the sisters in the Prague hospital, reports this fact and its explanation in the last number of the *Deutsche medizinische Wochenschrift*. (Trunececk and Baudouin also discuss the teratologic aspect of the case in the *Semaine Médicale*, May 18.) Basch regards the influence of the sympathetic nervous system on the secretion of milk as small. The rôle of the sympathetic is especially shown in the transmission of reflexes in sucking or milking which are necessary to a uniform continuous activity of the mammary glands. The essential specific activity of the mammary glands is independent of the nervous system. According to Basch, the growth of the breasts is occasioned by stimulant substances which are present in the ovary after impregnation, while the initiation of the secretion of milk is brought about by stimulating substances which may be obtained from the expelled placenta. According to his opinion the secretion of milk in the non-pregnant twin is to be explained by the fact that we have to do with two individuals living in parabiosis in whom the necessary stimulus to the production of lactation generated by the pregnant sister was carried by the common blood stream to the other sister with positive effect. Whether this idea will be sustained by other investigators remains to be seen.

VIENNA LETTER

(*From Our Regular Correspondent*)

Vienna, June 3, 1910.

The Weather in May and Public Health

This last month of May was most unusual on account of the weather and its effects on the general health. The first half of the month was characterized by excessive rainfall, which exceeded that in any month of May since reliable records have been kept in this country (1775). It amounted to 184 mm. Nevertheless, the general health was excellent, especially among children. A complete absence of gastro-intestinal disturbance was noted, and also among the adults. Vital statistics for this period show remarkably favorable figures. When on May 15 fine weather set in and continued without interruption till the end, with high summer temperature, at once the number of diseases went up by leaps and bounds; summer diarrhea set in and numerous infectious diseases were reported, especially pertussis, measles and diphtheria. In adults disturbances of the respiratory organs were common. Another remarkable feature was the belated appearance of the so-called hay-fever, which in this country generally is observed already in the last days of April, while this year the most dangerous time for these poor patients, the budding of chestnuts, passed off without much harm to them. Furthermore, the wet weather at the beginning of our summer has caused enormous numbers of mosquitoes, which for many years were not found around Vienna, to invade all country places, so that at present they are veritable pests in such places. No appreciable influence has been hitherto noticed on the appearance of epidemic cerebrospinal meningitis and poliomyelitis, which have been seen sporadically during the winter. It was feared that the moist weather would cause a rise in the number of those cases, but hitherto, luckily, nothing of this kind has happened.

Report of Vienna General Policlinic

The report of the Policlinic in Vienna contains the following interesting figures: In 1909, not less than 76,950 new patients were admitted, 5,000 more than 1908. Of these 5,011 were patients who stayed 52,133 days altogether in the wards. Besides, 854 children were admitted, 17,000 minor operations were performed in the out-patient departments, while 970 major operations were performed on the in-patients. The mortality of the operations was only 5 per cent., while the mortality of the entire hospital was 10.5 per cent.; 59 per cent. of the patients were discharged cured. An interesting feature was the fact that diphtheria, of a light nature only, was observed, the mortality being 4 per cent. This is quite unusual and must be ascribed only to an accidental influence, as otherwise the mortality is from 8 to 12 per cent., even with antitoxin, which is here the routine treatment. The expenditure exceeds the income by 51,000 kronen, so that the deficit is keenly felt. There were altogether 220 students (mostly duly qualified doctors) in the wards and out-patient departments; 60 per cent. were English or American, and a good many lectures were delivered in English. The medical staff of the Policlinic, which comprises special professors for all branches of medicine, numbers 21 professors and 80 physicians and assistants. The hours of attendance on the patients vary from 8 a. m. till 8 p. m., so that during practically all the day specialist help is available for all patients and diseases.

Pharmacology

PHARMACEUTICAL MANUFACTURERS AND THE GREAT AMERICAN FRAUD

How Pharmaceutical Houses Aid and Abet the Nostrum Evil

At various times we have given more or less complete accounts of the prosecutions the United States Government has brought against nostrum exploiters under the Food and Drugs ct. One of the more recent of these, while of comparatively ittle interest *per se* is of importance to the medical profession, because of certain elements connected with it. The case is known technically as "Notice of Judgment No. 284" and deals with the "Alleged Misbranding of Danderine." The gist of the case is as follows: Casks of Danderine—a widely advertised "hair tonic"—were shipped in carload lots from Michigan to West Virginia, where the product was bottled, labelled and put in condition to be retailed. Danderine contains a percentage of alcohol which, while given on the labels of the bottles in which it is sold, was not stated on the casks in which the preparation was shipped in bulk. The government sought to confiscate, under the Food and Drugs Act, 65 casks thus shipped because the quantity or proportion of alcohol in the casks was not stated. The Knowlton Danderine Company resisted the confiscation and the court upheld the company's claim.

The point in this case which is—or should be—of interest to the medical profession is to be found in the "statement of facts" presented by the Knowlton Danderine Company in its own defense. Here it is said that: "Parke, Davis & Co., who are mentioned in the said libel as shippers . . . are under contract with the said Knowlton Danderine Company . . . to compound the said formula . . ." Elsewhere it is stated: "Parke, Davis & Co. were . . . the manufacturing agents, under contract, of the owner, the Danderine Company . . ."

This evidently means that Parke, Davis & Co., who are generally supposed to manufacture only "ethical" preparations—proprietary or otherwise—and as such to desire the respect and good wishes of the medical profession, are in the business of furnishing the supplies for nostrum vendors. What Danderine is, it is hardly necessary to specify. The widely distributed advertisements of this "hair tonic" nostrum with the slogan: "Danderine Grows Hair and We Can Prove It" are sufficiently well-known to all who read to make a lengthy disquisition on the product unnecessary.

It is interesting in this connection to note that according to newspaper dispatches the Danderine Company has absorbed the Sterling Remedy Company, which exploits "Cascarets." Three years ago a physician, who is also a pharmacist, wrote to the *Medical World* regarding the manufacture of Cascarets:

> ". . . I have positive evidence, which I will gladly submit, that P., D. & Co., make all of them [Cascarets], and that they have a contract with the Cascaret people not to make anything similar for any one else."

In the circular which comes in the Danderine packages two other "specialties" are advertised: "Neuralgine" for "sick, weak, tired nerves" and "Drake's Palmetto Compound" for "weak stomachs, sluggish livers, disordered kidneys" and various other derangements of the system. The question naturally arises, are these, too, shipped in casks from Parke, Davis & Co., and merely bottled and labelled in West Virginia?

Not that the Danderine case is the first one in which Parke, Davis & Co. have been exposed as manufacturers of nostrum supplies. "Vitaopathy" a method of "treatment" practised by the notorious New York Institute of Physicians and Surgeons in the person of "Prof." Adkin and apparently consisting of "absent treatment" and pills, was finally put out of business by a fraud-order from the post office department. The concern used to advertise:

> "In Professor Adkin's laboratory, his chemists are daily engaged in extracting the life-and-health-giving principle from rare vegetables, fruits and plants."

"Prof." Adkin had no laboratory; his chemists, according to the government report, were Parke, Davis & Co., from whom he purchased the tablets which formed part of his stock-in-trade of quackery.

The Nutriola Company of Chicago was declared fraudulent by the postal authorities and a full account of the methods of this fake medical concern appeared in THE JOURNAL, April 28, 1906. Nutriola was advertised as:

> "The greatest Chemical-Medical Preparation ever prepared by the skill of man."
>
> "Nutriola and Nature are the only invincible conquerors of diseases ever known."

The promoter of this scheme was one Edward F. Hanson, who was questioned by the government inspectors regarding the manufacture of the Nutriola nostrum. Quoting from the government report:

> "*Q.* Please name the chemists who now manufacture the remedies of the Nutriola Company."
>
> "*A.* Parke, Davis & Company, Detroit; E. L. Patch Manufacturing Company, Stoneham, Mass.; Seabury & Johnson, New York."

Not that the course pursued by Parke, Davis & Co. is by any means an exceptional one in the pharmaceutical world. It may be recalled that THE JOURNAL has previously referred to the fact that Sharp & Dohme are reported to make or to have made the "Getwell Tablets" for the "patent medicine" concern which exploits the nostrum; and that Frederick Stearns & Co. make or did make the widely advertised "cures" Shac and Zymole Trokeys also has been mentioned. That Seabury & Johnson made preparations for a fake medicine concern was brought to light by Mr. Adams in the "Great American Fraud" series. And unquestionably there are many others. The attitude taken by such houses seems to be that they are willing to furnish anything in the pharmaceutical line that anyone is willing to pay for, whether it is for legitimate use of the physician or pharmacist or for furthering the business by which the ignorant or gullible sick are humbugged and defrauded.

[CONTRIBUTION FROM THE CHEMICAL LABORATORY OF THE AMERICAN MEDICAL ASSOCIATION.]

MOTHERSILL'S SEASICK REMEDY

W. A. Puckner and W. S. Hilpert

While, from published analyses, the composition of such classes of proprietary remedies as cough cures, headache-powders, etc., has become well known, very little has appeared regarding the nature of nostrums advertised to prevent seasickness. For this reason the examination of Mothersill's Seasick Remedy, as an extensively exploited representative of this class, was undertaken in the Association laboratory. The manufacturers, "Mothersill Remedy Co., Ltd., Detroit," send out circulars containing the most extravagant and sweeping statements regarding the efficacy of their remedy. For instance:

> "The only remedy which stops instantly and prevents, in every case, when taken according to directions, seasickness, carsickness and nausea caused by motion, climbing, etc."
>
> ". . . It is a great stomach strengthener."
>
> "No bad after-effects are ever produced by this remedy."
>
> "Mothersill's Seasick Remedy has never been known to fail in a single case."

These statements are backed by the "guarantee" of the manufacturers as follows: "We guarantee the successful action of Mothersill's Seasick Remedy in every case."

Further to inspire confidence, an analytical report and testimonials are included in the advertisements. The chemist reports that he found neither "opium, morphin, cocain or any other alkaloid——." The testimonials are principally in the form of reprints from newspapers, mostly of English origin, and are as lavish in their praise of the remedy as the firm's own advertisements.

The preparation, as purchased on the market, comes in small boxes containing sixteen capsules, half of them containing a pink powder and the remainder a brown powder. The capsules are wrapped in tin-foil and packed with a circular and the reproduction of the analyst's report mentioned above. The cover of the container bears the name and manufacturer of the preparation with statements as to its use. The under side of the box bears the "guarantee" and special directions for the use of the remedy in the Irish and the English channels.

The pink powder possesses an odor resembling camphor, and when placed on the tongue produces a slight anesthesia. It is partly soluble in water and partly in chloroform. Qualitative examination[1] indicated the presence of chlorbutanol (acetone-chloroform; chloretone; methaform), caffein, milk-sugar and a fatty acid. Quantitative analysis demonstrated that 100 parts of the material contained approximately:

Chlorbutanol	46.1 per cent.
Caffein	7.9 per cent.
Milk-Sugar	27.0 per cent.
Fatty acid	18.2 per cent.
Undetermined	0.8 per cent.

The brown powder possessed the same general properties as the pink and was found to contain chlorbutanol, caffein, powdered cinnamon and a fatty acid. The quantitative analysis showed that 100 parts of this brown powder contained approximately:

Chlorbutanol	45.6 per cent.
Caffein	8.3 per cent.
Cinnamon, powdered	24.8 per cent.
Fatty acid	20.3 per cent.
Undetermined	1.0 per cent.

From the above it will be seen that the chief constituent of this preparation is chlorbutanol, a substance some years ago introduced as a substitute for cocain and used as a local anesthetic: it has been recommended as a preventative of nausea.

EDITORIAL NOTE: It is evident from the analysis that in this nostrum we have but another example of a scheme that is as old as quackery itself—selling a well-known remedy under another name and investing it with virtues that are little short of miraculous. While chlorbutanol—better known under the proprietary names of chloretone and methaform—has been used to some extent and with a limited degree of success in the treatment of sea-sickness, it is evident that if it were the marvelous specific against *mal de mer* that the exploiter would have us believe, its use would long ago have become universal. This nostrum, like all others, depends for whatever popularity it may have on several factors. The first, and largest, is the universal tendency to give any therapeutic agent—worthy or worthless—the credit that rightly belongs to beneficent Nature. Second is the psychic element, which is enhanced by the exaggerated but very positive claims that are made for all nostrums, strengthened by the fact that the victim is paying ten times more than the thing is worth. The element of suggestion is still further augmented by the device of administering two powders of different colors containing essentially the same substances. Last, and least, the fact that the principal ingredient has a therapeutic value in selected cases.

Correspondence

Snake Poisoning—A Case of Plagiarism

To the Editor —My attention has just been called to an article entitled "Practical Consideration of Snake Poisoning," by Benjamin H. Orndorff, B.A., M.D.," Instructor in Pathology, Chicago College of Medicine and Surgery, Pathologist to Frances Willard Hospital, Chicago." This article was published in the *Medical Standard*, Chicago, September and December, 1909, pages 476 to 481 and 637 to 640. There was published by me in the *Archives of Internal Medicine*, Chicago, volume 1, June, 1908, pages 516 to 570, a paper entitled "Snake Poisoning in the United States; a Study Based on an Analysis of 740 Cases." This paper was the result of a large amount of work, which involved not only an examination of the literature but a collection, by correspondence with physicians practicing in the South, of a considerable number of unpublished cases. This article was commented on editorially by THE JOURNAL, July 11, 1908, page 132, and later reviewed in the Department of Therapeutics (THE JOURNAL, Aug. 8, 1908, p. 498).

The article by Dr. Orndorff, mentioned above, seems to be based almost entirely on my article published in the *Archives of Internal Medicine*. The outline and the division of the subject are identical. Not only paragraphs, but whole columns are exactly and literally quoted—without quotation marks. The conclusion and summary of my article, divided into ten numbered paragraphs, has been appropriated as a whole, without change and again without quotation marks. Dr. Orndorff makes absolutely no mention of my communication, gives absolutely no credit. Indeed, in one of the few paragraphs not taken bodily from my paper he states (in substance) that his article is based on a careful study of the literature!

It would seem that such a flagrant case of plagiarism as this should not go unnoticed, constituting, as it does, a disgrace to medical journalism. I trust THE JOURNAL will see its way clear to compare the two articles mentioned. Any comment it might see fit to make would be appreciated.

PRENTISS WILLSON, M.D., Washington, D. C.

[Proof of the above letter was submitted to Dr. Orndorff, who replies:]

The article is a publication of abstracts taken from several original articles appearing in current literature. These abstracts I prepared to assist me in giving a lecture on the subject and were intended to be the basis of an article for publication; however the abstracts, as they stood, appeared in the *Medical Standard* without my seeing a proof sheet for approval, indeed, the first portion appeared while I was in Europe, the second about fifteen days after my return.

All credit to the men writing the original articles was unfortunately omitted and the publication, as it stands, appears as a clumsy combination of plagiarism and ignorance on the part of the author. While I am certain there is nothing I can say or do that will amend the injustice inflicted on the men whose brains have developed the material from which these abstracts were taken, still it would please me to state in the columns of THE JOURNAL of the American Medical Association that the most excellent monograph by Dr. Prentiss Willson, "Snake Poisoning in the United States; a Study Based on the Analysis of 740 Cases," appearing in the *Archives of Internal Medicine*, June, 1908, furnished the outline and much of the information found in my abstracts, while the summary and conclusion were copied entirely.

On receiving the reprints from this publication, I immediately observed the unfortunate state of affairs, and personally called at the office of the *Standard* to negotiate for another set of reprints which should contain the two omitted paragraphs, quotation marks and many other corrections, hoping that by the corrected print I might offset in a small measure the gross mistakes. On learning the cost of such alterations, I decided to ignore the entire affair and to dispose of the reprints without distribution.

---

[1] The details of the analysis will be sent on receipt of a stamped, addressed envelope; they will also be published in the annual report of the Chemical Laboratory.

In conclusion I wish to express my profound regret for this mistake and trust that this explanation and apology may serve as a slight atonement of the injustice imposed on these men, for whose labor I possess the highest regard.

B. H. Orndorff, M.D.

[Comment: We suggest that those who are interested in the subject of journalistic plagiarism should examine the two articles. They can then decide for themselves whether or not the explanation explains.]

Hay-Fever Not a Contraindication to Antitoxin

To the Editor:—The note in the Medicolegal department (June 18, 1910, p. 2094), in regard to the use of tetanus antitoxin on patients who have hay-fever, leads me to say that I have used the antitoxin as a prophylactic measure on several occasions. Many patients have suffered in varying degree from hay-fever, yet in no case have I seen any untoward effect follow its use.

I myself suffer severely from hay-fever during August and September of each year. Last September I received an injury which made it seem wise to use a single large injection of the antitoxin. At the time I was suffering severely from hay-fever. I suffered no inconvenience whatsoever following the injection.

There is at times so much at stake as a result of injuries which tetanus may complicate, and prophylactic treatment is so very satisfactory, that I should not in the least hesitate either to use the antitoxin on a hay-fever patient or to have the antitoxin used on myself as frequently and in as large doses as might seem to be useful.

Edward M. Colie, Jr., M.D., New York.

A New Word for Vaccine

To the Editor: There is need of a new descriptive word in our nomenclature. "Vaccine," from *vacca*, "a cow," is a misnomer when applied to serums taken from any other source, man, horse, goat, guinea-pig or rabbit; and doubtful, if a culture is made from a broth. We need a word which defines the character of the remedies now so much used as antidotes. We reverse the old dictum of the homeopathic school: "Similia similibus curantur," and say "Like kills like;" and this likeness of remedy to disease should be asserted.

My own suggestion for the new word is "viroid," i. e., like the virus for which it is the antidote. This name is distinctive, and it follows the analogies of medical language. It claims to combat a disease with its specific antidote. "Viroid" would be the name of the type of remedy, and a prefix would define the special remedy.

We may hope before long to have in use a pneumonia viroid, an influenza viroid, a scarlatina viroid, as we have now a rabies viroid.

"Antitoxin," by popular and professional use, is assigned to diphtheria. Itself a cumbrous word, any prefix or combination would make it worse. "Viroid" is definite, is descriptive, and is an easy helpmate when yoked with any named disease.

Henry Freeman Walker, New York.

Miscellany

Constriction Hyperemia in Local Prophylactic Treatment of Rabies.—Fermi and Cano report that the results of their experimental research suggest the possible advantage of applying a constricting elastic band, according to Bier's technic, to a limb that has been bitten by an animal suspected of rabies. Fermi applied the constriction from 1 to 4 or even 5 hours after injection of a 1 per cent. emulsion of fixed virus and maintained it for from 1 to 12 hours. All the animals thus treated survived, while the controls all died. Cano reports from Suez that in similar experiments 8 of the 9 dogs survived, that is 88 per cent., while only 55 per cent. were saved out of 9 rabbits and dogs treated by searing the lesion with a hot iron. Fermi also was able to save only 50 per cent. of those treated with the hot iron. Cano's report is published in the *Centralbl. f. Bakt.*, March 2, 1910, liv, page 37.

Diagnosis of Morphin Addiction by the Leucocytes.—Achard, Bénard and Gagneux state that it is possible by examination of the leucocytes to recognize morphin intoxication, to supervise the effects of treatment of morphin addiction and to distinguish between morphin and heroin intoxication. In their communication on the subject in the *Bull. Soc. Méd. des Hôp. de Paris*, 1910, xxxvi, 958, they relate a number of experiences with clinical, experimental and chemical tests showing the action of morphin on the leucocytes. The resisting power and activity of the leucocytes are rapidly reduced by injection of morphin except in those accustomed to the drug; in them there is no modification of the leucocytes after a test injection of morphin. The properties of the leucocytes are determined by the cytolytic action of a hypotonic salt solution; the mechanical activity being determined by their capacity of absorption of a stain (neutral red) or of foreign bodies (sterilized thrush fungus). The findings in 42 cases are given in detail.

Blister Method for Transplanting Epidermis.—A. Tedeschi had occasion to treat a patient with extensive burns who refused to permit Thiersch flaps to be taken from elsewhere to cover the defect. After excluding kidney trouble, Tedeschi applied a caustic to the skin over the desired area for a few hours and then cut the skin of the resulting blister to use for flaps, which he was able to make of the exact size and shape desired. The defect thus covered with the flaps was protected with perforated rubber tissue with moist gauze above. In his communication on the subject in the *Semana Medica*, 1910, xvii, 247, he states that the results were very good. The superficial layer of the transplanted flaps was thrown off in a few days, but the epithelial layer left soon grew to cover the raw area under the usual measures.

Queries and Minor Notes

Anonymous Communications will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

VERMIN AS CARRIERS OF DISEASE

To the Editor:—Please give references to literature on common insects and animals as carriers of diseases to man.

THYMINIC ACID

To the Editor:—Where can I obtain thyminic acid, which has been used apparently with success in gout by Dr. Fenner of England? I cannot find it listed in any catalogues of American drug houses. 2. Has it been used in this country with any success?

F. H. NORWOOD, Prague, Okla.

ANSWER.—1. Thyminic acid is also known under the name "solurol," a name which was given to it by its discoverer, Minkowski, and which appears not to be proprietary. We presume it can be obtained through the regular channels of the drug trade.

2. An article describing the use of thymic acid in gout by E. Schmoll, appears in THE JOURNAL, April 29, 1905, p. 1348, but we find no reference to it in American literature since that time. Schmoll treated about 30 patients with it with favorable results. The term thymic acid as used by Schmoll refers to the substance which is more properly known as thyminic acid. A general account of this substance was given in THE JOURNAL, Aug. 22, 1908, p. 692. In an article on "The Pathology and Therapy of Gout" (*Therapie der Gegenwart*, February, 1909), F. Umber makes the following statements: "We have used solurol in gouty patients with exact observation of the metabolism without any clinical effect and without any effect on the curve of uric acid excretion." It is well to remember, as Umber remarks, that there is scarcely any so-called gout remedy which has not been credited by this or that author with brilliant success.

The Public Service

Medical Department, U. S. Army

Changes for the week ended June 25, 1910.

Oliver, Robert T. E. S. D., surgeon, returned to Fort Hamilton, N. Y., from temporary duty at Fort Hancock, New Jersey.

Griffis, F. C., M. R. C., left station with 4th Field Artillery to Fort D. A. Russell, Wyo, Target and Maneuver Reserve.

Long, Charles J., dental surgeon, reports for temporary duty at Fort Andrews, Mass.

Gunckel, George I., dental surgeon, reports for temporary duty at Fort Screven, Ga., left Fort Sarrancas, Fla., June 10, 1910.

Ferenbaugh, Thomas L., M. R. C., reported at Fort D. A. Russel, Wyo., for temporary duty.

Gray, William W., col., reported for duty as Chief Surgeon, Headquarters Department of Dakota, St. Paul., Minn.; left St. Paul, Minn., June 18, 1910, on 30 days' leave of absence.

Oliver, Robert T., E. S. D. S., will proceed to the *camp of instruction* to be held at Gettysburg, Pa., to arrive July 1 for dental service during the encampment.

Hall, William E., M. R. C., on arrival at San Francisco, will proceed to Whipple Barracks, Ariz., for station.

Clark, John A., capt., on arrival at Seattle, Wash., will proceed to Plattsburg Barracks, N. Y., for station.

Roberts, William M., major., granted 3 months' leave of absence.

Pinkston, O. W., capt., reported for temporary duty at Fort D. A. Russel, Wyo.

[illegible] lieut., honorably discharged from the service of [illegible]

[illegible] major, left Fort MacKenzie, Wyo., on 10 da[illegible]

[illegible] R. C., ordered to active duty in the service of the United States, and will proceed to Fort D. A. Russel, Wyo., for station and duty.

Warriner, B. B., M. R. C., granted 10 days' leave of absence.

Banister, William B., lieut. col., will, in addition to his duties at Fort Snelling, Minn., take charge of the office of chief surgeon, Department of Dakota, St. Paul, Minn., during the absence of Colonel William W. Gray, Medical Corps.

Sharpe, Herbert H., M. R. C., ordered to proceed from Fort Jay to Fort Niagara, N. Y., for temporary duty.

Holmes, R. W., M. R. C., left Plattsburg Barracks, N. Y., on 10 days' leave.

Clark, John A., capt., granted leave of absence for 1 month.

Coffey, Albion McD., M. R. C., granted leave of absence for 1 month.

Coe, Henry C., M. R. C., ordered to active service and will proceed to Camp of Instruction, Gettysburg, Pa., *for duty*.

Hughes, Leonard S., M. R. C., ordered on expiration of his present leave of absence to proceed to Fort D. A. Russel, Wyo., for station and duty.

Pinquard, Joseph, M. R. C., granted leave of absence from June 22 to Sept. 9, 1910, at which date he is honorably discharged from the service.

Long, Charles J., dental surgeon, ordered to proceed at the proper time to Pine Camp, Jefferson County, N. Y., for dental service during the Camp of Instruction.

Snyder, Henry D., major, granted 30 days' leave of absence; ordered to proceed to New York City, on official business pertaining to the Medical Department of the Army.

Medical Corps, U. S. Navy

Changes during the week ended June 25, 1910:

Woodland, E. E., acting asst.-surgeon, appointed acting asst.-surgeon from June 18, 1910.

Fitts, H. B., medical inspector, detached from command Naval Hospital, Pensacola, Fla., and ordered to continue other duties.

Pryor, J. C., surgeon, ordered to command the Naval Hospital, Pensacola, Fla.

Shipp, E. M., surgeon, detached from the Naval Recruiting Station, N. Y., and ordered to the Naval Medical School Hospital, Washington.

Asserson, F. A., surgeon, detached from the Naval Hospital, Portsmouth, N. H., and ordered to duty at the Naval Hospital, Boston.

Heiner, R. G., P. A. surgeon, ordered to duty at the Naval Hospital, Norfolk, Va.

Haynes, J. P., surgeon, detached from the Navy Yard, Norfolk, Va., and ordered to the Naval Recruiting Station, and the Naval Station, New Orleans.

Stuart, A., P. A. surgeon, ordered to duty at the Naval Hospital, Boston.

Jenness, B. F., P. A. Surgeon, detached from the Naval Recruiting Station, Buffalo, N. Y., and ordered to the Naval Hospital, Portsmouth, N. H.

Howard, J. V., A. A. surgeon, ordered to duty at the Naval Hospital, Philadelphia.

Hightower, C. C., A. A. surgeon, ordered to duty at the Naval Hospital, New York.

U. S. Public Health and Marine-Hospital Service

Changes for the seven days ended June 22, 1910:

Glennan, A. H., assistant surgeon-general, granted 1 month's leave of absence from July, 1910.

Cofer, L. E., assistant surgeon-general, granted 4 days' leave of absence from June 22, 1910.

Wertenbaker, C. P., surgeon, granted 4 days' leave of absence from June 27, 1910.

Wille, C. W., P. A. surgeon, detailed to attend the joint meeting of the Ohio State Board of Health with local boards of health to be held in Cleveland, Ohio, June 30-July 1, 1910.

Long, J. D, P. A. surgeon, relieved from duty in the Hygienic Laboratory and detailed for duty in the Bureau as assistant surgeon-general in charge of the Division of Domestic (Interstate) Quarantine, effective June 16, 1910, Paragraph 12, Service Regulations.

Stimson, A. M., P. A. surgeon, granted 4 days' leave of absence from June 15, 1910, under Paragraph 191, Service Regulations.

Roberts, Norman, P. A. surgeon, granted 1 day's leave of absence June 13, 1910, under Paragraph 191, Service Regulations.

Frost, W. H., P. A. surgeon, granted 2 days' leave of absence en route to station.

Mullan, E. H., P. A. surgeon, granted 13 days' leave of absence from June 17, 1910.

Stiles, C. W., Professor, Chief Division of Zoology, Hygienic Laboratory, detailed to attend the annual meeting of the Medical Society of North Carolina, to be held at Wrightsville Beach, June 23, 1910.

Delgado, J. M., acting asst.-surgeon, granted 26 days' leave of absence from July 1, 1910.

Hough, J. Spencer, acting asst.-surgeon, granted 30 days' leave of absence during the calendar year, 1910.

Hunter, W. R., acting asst.-surgeon, granted 10 days' leave of absence from June 18, 1910.

O'Neill, A. A., acting asst.-surgeon, granted 3 days' leave of absence without pay from June 10, 1910, under Paragraph 210, Service Regulations.

Marriages

ROBINSON BOSWORTH, M.D., Calais, Me., to Miss Mary Neill of Boston, June 21.

JOHN MERLIN ALFORD, M.D., Galva, Ill., to Miss Shirley Foote of Chicago, June 17.

CHARLES OGILVY, M.D., to Miss Evelyn Hunter, both of New Rochelle, N. Y., June 15.

LOUIS ROSENTHAL, M.D., to Miss Elizabeth Kass, both of New York City, June 7.

CHARLES WILSON DOUGHTIE, M.D., Norfolk, Va., to Miss Alice Glenn Smith, June 18.

WILLIAM F. BEITSCH, M.D., to Miss Mabel McDanel, both of New Brighton, Pa., June 14.

HENRY SYMES STINSON, M.D., to Miss Mary H. Broadwell, both of Berwyn, Ill., June 18.

ETTA BARKDOLL, M.D., Greencastle, Pa., and J. Roy Selsam, at Hagerstown, Md., June 11.

WILLIAM GARFIELD FOX, M.D., to Miss Susan Lucretia Burg, both of Lancaster, Pa., June 21.

THOMAS WORTH KELLER, M.D., to Miss Hannah B. Jones, both of Pittsburg, Pa., recently.

FRANCIS C. GOLDSBOROUGH, M.D., to Miss Mollie Pitcher Cook, both of Baltimore, June 8.

William Roy Elgin, M.D., Ruleville, Miss., to Miss Zerah Harpole of Europa, Miss., June 11.

Charles F. Daniels, M.D., Tiffin, Ohio, to Miss Olga Mary Hierholzer of Celina, Ohio, June 14.

Howard T. Clarke, M. R. C., U. S. Army, to Miss Elinor L. Tracy, at Fort Thomas, Ky., June 7.

Arthur Clarkson Smith, M.D., Oakland, Cal., to Miss Algae Margaret Hurd of Lodi, Cal., June 4.

Washington Budd Sager, M.D., Woodstock, Va., to Miss Helen Newman, at Woodstock, June 14.

Charles Butterfield, M.D., Rock City, Ill., to Miss Charlotte Heath of Lawrence, Mich., recently.

John Royer Laughlin, M.D., Hagerstown, Md., to Miss Myrtle F. Binkley, at Hagerstown, June 15.

Walter Everett Deering, M.D., Hollywood, Cal., to Miss Lillian Rose Moody, at Hollywood, June 21.

George William Kirmse, M.D., Frazee, Minn., to Miss Aldine Jacobsmeyer of Clayton, Mo., June 15.

Alfred Curtis Rice, M.D., McSherrystown, Pa., to Miss Violet M. Smith, at McSherrystown, June 14.

Harold Bailey, M.D., to Miss Mabelle Rague, both of Charles City, Iowa, at Waterloo, Iowa, June 15.

Albert Ege Craig, M.D., Washington, D. C., to Miss Azelia DeGrange Jones, at Shepherdstown, W. Va., June 16.

Clarence W. Russell, M.D., Lamar, Colo., to Mrs. Abby C. Howe of Laporte, Ind., at Logansport, Ind., recently.

Charles Hatch Stoddard, M.D., Milwaukee, Wis., to Miss Eloise Marie Jackson of Birmingham, Ala., June 25.

Harvey B. Sanborn, M.D., to Miss Bernice Esther Monk, both of Providence, R. I., at Campello, Mass., June 10.

Ernest L. Ruffner, M. C., U. S. Army, to Miss Jessie B. Bowen of Buffalo, N. Y., at Mount Vernon, N. Y., June 14.

William Worthington Herrick, M.D., New York City, to Miss Emily Elizabeth Schwab of Ossining, N. Y., at Scarboro, N. Y., June 15.

Deaths

William Henry Seaman, M.D. (Hon.) Howard University, Washington, D. C., 1883; professor of chemistry and toxicology in Howard University; a fellow of the American Association for the Advancement of Science; corresponding member of the Maryland Academy of Sciences; member of the Biological, Geographical and Chemical societies of Washington; president of the Washington Microscopic Society in 1900, and secretary of the American Microscopical Society from 1891-1894; principal examiner of the United States Patent Office, Washington; died in that city, June 11, from arteriosclerosis and acute cardiac dilatation, aged 72.

John Wesley Tope, M.D. Rush Medical College, 1870; a member of the American Medical Association; a veteran of the Civil War; superintendent of the Asylum for the Insane at Dunning for five years; member of the surgical staff of Cook County Hospital for fourteen years; founder of the Oak Park Hospital; president of the Alumni Association of Rush Medical College; president of the Aux Plaines branch of the Chicago Medical Society; died at his home in Oak Park, June 18, aged 65.

Meyer Herman, M.D. Columbia University, Washington, D. C., 1891; contract surgeon U. S. Army, 1898 to 1901; assistant surgeon, U. S. Volunteers; a veteran of the Spanish-American War, who went to the Philippines with the Thirty-eighth Volunteer Infantry as a captain-surgeon after a season in Cuba combating yellow fever; of Manila; died in St. Paul's Hospital at that place, May 12, from diabetic coma, following an operation for appendicitis, aged 49.

John Francis Bennett, M.D. Michigan College of Medicine and Surgery, Detroit, 1892; a member of the American Medical Association; professor of physical diagnosis and clinical medicine in his alma mater; U. S. pension examining surgeon; a resident of Detroit and coroner of Wayne county; died at the home of an aunt in Northville, Mich., June 19, from valvular heart disease and heat prostration, aged 45.

Jules A. Simon, M.D. University of California, Medical Department, 1875; Faculty of Medicine, Paris, France, 1883; a member of the Medical Society of the State of California; at one time president of the Board of Health of San Francisco; and a member of the staff of Mount Zion Hospital; died from heart disease while ascending Mount Vesuvius Italy, June 8.

E. Rose Dorsett, M.D. Jefferson Medical College, Philadelphia, 1868; a member of the Medical Society of the State of North Carolina; coroner of Rowan county for thirty years; died at his home in Salisbury, June 16, from pericardial effusion, aged 76.

Edward D. Swift, M.D. Louisville (Ky.) Medical College, 1894; a member of the Indiana State Medical Association; of Macy, Ind.; died at Oskaloosa, Kan., where he had gone for his health some weeks ago, June 10, from heart disease, aged 39.

Robert Booth, M.D. University of Michigan, Department of Medicine and Surgery; 1867; a member and chairman of the Millbury, Mass., Board of Health; died at St. Vincent Hospital, Worcester, June 14, from cystitis and heart disease, aged 69.

John Belton O. N. Harrington, M.D. Louisville (Ky.) Medical College, 1879; a member of the Mississippi State Medical Association; of Crawford, Miss.; died at the home of his sister in that place, June 13, from chronic gastritis, aged 57.

Charles Herbert Boxmeyer, M.D. Cornell University Medical College, 1906; at one time state bacteriologist of Florida and later city bacteriologist of Sacramento, Cal.; health officer of Palo Alto, Cal.; died at that city, June 13, aged 34.

David D. Stewart, M.D. Jefferson Medical College, Philadelphia, 1879; a pioneer practitioner of Johnson county, Iowa; a veteran of the Civil War; died at his home in North Liberty, Iowa, June 10, from heart disease, aged 79.

Randall Doyle Bibber, M.D. Medical School of Maine, Brunswick, 1871; a member of the American Medical Association; three times mayor of Bath, Maine; died at his home in that city, June 9, from chronic nephritis, aged 64.

Burwell Philip Goode, M.D. Medical College of Ohio, 1858; a member of the American Medical Association; a practitioner of Cincinnati for fifty years; died at Cincinnati, April 23, from cerebral arteriosclerosis, aged 77.

Wesley A. Cormack, M.D. Eclectic Medical Institute, Cincinnati, 1874; for more than thirty years a practitioner of Cherryvale, Kan.; died at his home in that place, June 9, from heart disease, aged 71.

Randall Williams, M.D. Albany (N. Y.) Medical College, 1848; a practitioner of LeRoy, N. Y., for half a century, and said to have been the oldest physician in Genesee county; died at his home, June 10, aged 85.

Edward Goodell Larrabee, M.D. Dartmouth Medical School, Hanover, N. H., 1909; a member of the staff of the Maine State Sanatorium, Hebron; died at that institution, June 12, from tuberculosis, aged 24.

Robert Newton Hawley, M.D. College of Physicians and Surgeons, New York City, 1879; a veteran of the Spanish-American War; formerly of Milwaukee, Wis.; died at Baltimore, June 13, aged 54.

Levi D. Tebo, M.D. Hahnemann Medical College and Hospital, Philadelphia, 1873; a practitioner of Bordentown, N. J., for thirty years; died in that city, June 14, from cardiac degeneration, aged 65.

Allen P. Mitten, M.D. Rush Medical College, 1867; Bellevue Hospital Medical College, New York City, 1873; formerly of Columbia City, Ind.; died at his home in Seattle, Wash., June 13, aged 65.

William Kennedy Brown, M.D. Jefferson Medical College, Philadelphia, 1845; a practitioner of medicine for sixty years; of Paris, Texas; died at the home of a son in Detroit, Texas, June 9, aged 91.

George P. Yost, M.D. Washington University School of Medicine, Baltimore, 1871; of Glen Rock, Pa.; died at the home of his son-in-law in Baltimore, June 12, from heart disease, aged 62.

John Winthrop Spooner, M.D. Harvard Medical School, Boston, 1871; a member of the American Medical Association; died at his home in Hingham, Mass., June 19, from paralysis, aged 64.

William Ekwurzel, M.D. Jefferson Medical College, 1868; a member of the Medical Society of the State of Pennsylvania; died at his home in Philadelphia, June 18, from heart disease, aged 67.

Ephraim S. Wynn, M.D. Jefferson Medical College, Philadelphia, 1872; of Camden, N. J., and Philadelphia; died at his residence in Camden, June 13, from heart disease, aged 61.

Thomas H. Ferguson, M.D. Washington University Medical Department, St. Louis, 1867; of Gridley, Cal.; died at the Rideout Memorial Hospital, Marysville, Cal., June 18, aged 73.

W. A. Martin, M.D. Medical College of Georgia, Augusta, 1843; of Cobbham, Ga.; while shaving, accidentally cut his throat so severely that he bled to death, June 12, aged 89.

Elijah Wilson Carney, M.D. Medical Department of Nashville and Vanderbilt University, Nashville, Tenn., 1892; of Shelbyville, Tenn.; died at that place, June 15, aged 40.

Robert A. Hammond, M.D. Jefferson Medical College, Philadelphia, 1876; of Monroe, Ga.; died at his home in that place, June 13, following an operation for appendicitis, aged 58.

Willis Brooks McMichael, M.D. Harvard Medical School, 1881; of Boston; died at the home of his mother in South Newcastle, Maine, June 11, from heart disease, aged 50.

William Eugene Trautwein, M.D. Bellevue Hospital Medical College, New York City, 1890; of New York City; died at his home, June 19, from heart disease, aged 44.

William Hendrik Horsley, M.D. California Eclectic Medical College, Los Angeles, 1900; of Manton, Cal.; died at that place, Oct. 14, 1909, from disease of the liver, aged 50.

Asa C. Wilton, M.D. University of Wooster, Medical Department, Cleveland, Ohio, 1882; died at the home of his sister in Youngstown, Ohio, June 16, aged 61.

Frank Cecil Fenhagen, M.D. College of Physicians and Surgeons, Baltimore, 1875; died at his home in Baltimore, June 13, from nephritis, aged 55.

William Alexander Simmons, M.D. Jefferson Medical College, Philadelphia, 1855; died at his home near Troy, N. C., recently, from nephritis, aged 82.

Henry W. Stork, M.D. Medical College of Evansville, Ind., 1878; died at his home in Holland, Ind., June 3, from cerebral arteriosclerosis, aged 59.

John M. McKnight, M.D. Tulane University, New Orleans, 1872; a confederate veteran; of Laredo, Texas; died at that place, June 19, aged 64.

Lorin North Pontius, M.D. Rush Medical College, 1881; of Canton, Ohio; died at a hospital in Gallipolis, Ohio, June 20, aged 56.

Daniel P. Durst, M.D. Jefferson Medical College, Philadelphia, 1850; died at his home in Wheatland, Cal., June 11, aged 85.

Stephen H. Fuller, M.D. Fort Wayne (Ind.) College of Medicine, 1880; died at his home in Pleasant Lake, Ind., June 21, aged 62.

Society Proceedings

AMERICAN SURGICAL ASSOCIATION

Annual Meeting, held in Washington, D. C., May 3-5, 1910

Operative Treatment of Tumors of the Hypophysis

Dr. A. E. Halsted, Chicago: A survey of the literature on the operative treatment of tumors of the hypophysis shows that many of the procedures proposed are based, not on clinical experience, but on observations made in the post-mortem room; therefore, the merits of these methods are still unproved. The routes of approach previously advocated have been the intracranial and the extracranial. I propose what I term the oronasal route, which I employed successfully in one case. It is a modification of the infranasal method of approach, but is without the trauma and disfiguration which must follow the König operation.

DISCUSSION

Dr. S. J. Mixter, Boston: In a patient operated on by the route suggested by Kanavel, there was a large cyst in the hypophysis filled with cholesterin and holding about one and a half to two ounces of fluid. The patient made a good recovery after the operation and his vision, which before was extremely poor, has been benefited.

Dr. Harvey Cushing, Baltimore: The various means of approach to the hypophysis do not make so much difference as does the matter of dealing with the structure when it is brought into view. The growth often becomes malignant, as is true of long-standing trouble with the thyroid, and it is conceivable that it cannot be entirely removed. In fatal cases it has often been found that only a mere fragment of the growth has been taken away. The operation in the first place has for its object the relief of pressure; the symptoms can be combated by the mere removal of the lower part of the sella turcica and the splitting of the capsule of the gland.

Dr. A. B. Kanavel, Chicago: Concerning the technical procedure in Dr. Halsted's cases, in the first one particularly the view could not have been better. The operation was very quickly done, the anterior wall of the sphenoidal sinus quickly removed, the bulging sella turcica opened, and a tumor protruding into the sinus was removed without difficulty. In the second case, the sella turcica did not bulge into the sinus, it was seen with more difficulty and was arrived at by anatomic deductions. In two cases there was considerable hemorrhage and I would suggest the elevation of the head during the operation. In the majority of cases it will only be necessary within the nose to remove the vomer and the anterior portion of the sphenoid in order to come down on the sella turcica.

Dr. Dean Lewis, Chicago: The tissue removed from the first case contains no elements which are ordinarily found in the anterior lobe or the pars intermedia, but is composed of stratified epithelium with a papillary arrangement, therefore we must assume that the tumor has probably developed from an epithelial inclusion which has not gone on to complete differentiation. The tissue removed from a second case came from the anterior lobe. In some sections the cell columns are cut parallel, long rows of cells resting between rather thick connective tissue trabeculæ; in other fields the cells have fused and in still other fields the fusion has become so marked that large groups of cells are found, hyperplasia apparently having ended in adenoma formation. It is important to recognize the complex structure of the hypophysis in making the anatomic diagnosis of tumors of this gland, and to remember that the cells of the anterior lobe, when growing rapidly tend to reproduce the structure of a sarcoma.

Benign Bone Cysts, Ostitis Fibrosa, Giant-Cell Sarcoma and Bone Aneurism of the Long Pipe Bones

Dr. Joseph C. Bloodgood, Baltimore: In many lesions technic is ahead of diagnosis. The development of technic is more rapid, because the results of faulty technic are immediate, while the development of diagnosis is more difficult, especially in tumors, because the results are more remote. Treatment of tumors which will assure the patient the greatest possibility of a permanent cure with the least mutilation will be accomplished only when surgeons have a better conception of the local growth of neoplasms. The so-called benign bone cyst may present itself in five forms: First, as a medullary cyst without any definite gross lining; second, as a similar cyst with a definite connective tissue lining which is easily stripped from the bony capsule; third, as a medullary mass of fibrous tissue with a small cyst; fourth, as the same medullary mass of fibrous tissue without any cyst formation; and fifth, as multiple medullary cysts. Among 89 cases of which 20 were personally observed, 69 belong to the variety of true localized bone cyst or ostitis fibrosa. The other 20 cysts have different etiologic factors, for example, cysts in enchondroma, in pure myxoma, in giant-cell sarcoma, in ostitis deformans; cysts due to subperiosteal ossifying hematoma, and callous cysts. At the exploratory incision in benign cysts there is always found a thin shell of bone; the contents of the cyst are usually of a dark-brown color and thin. The giant-cell sarcoma, of which I have studied 19 cases, can also be recognized at the exploratory incision. The medullary cavity is filled with a soft, hemorrhagic tissue resembling granulation tissue mixed with whitish areas which, when removed with the curette, come away in masses of irregular shape. This tumor also has been cured by *curetting. It is 8 years since I curetted from the medullary cavity of the upper end of the tibia such a tumor, and this patient has no evidence of recurrence today.* Patients have been cured even after repeated curetting; amputation is indicated only when the patient has allowed the tumor to grow to such a size that it has perforated the bone capsule and infiltrated the soft parts to such an extent that its complete removal would leave a functionless limb. The so-called bone aneurism is a much less frequent tumor and is distinctly malignant. It is a hematoma due to hemorrhage in the most malignant form of medullary spindle, round, or mixed-cell sarcoma, and I believe that in this stage of this tumor metastasis has already taken place, so that no harm could come from mistaking such a tumor for a bone cyst or giant-cell sarcoma. I have seen 3 cases, in one of which the patient was not saved by the highest amputation; in the second case amputation was refused; the third case was first treated as bone cyst, amputation was done later, but the patient died of metastasis.

DISCUSSION

Dr. Rudolph Matas, New Orleans: In one case in which, after removal of a giant-cell sarcoma from the humerus, there was a large cavity, I used about an ounce and a half of Mosetig cement, and the patient later developed extreme symptoms of iodoform poisoning, from which he recovered in 10 days, and the arm healed with a perfect contour of the bone. I believe that in Beck's paste we have a most valuable means of filling up cavities, it being superior in my opinion to any other paste.

Dr. William L. Rodman, Philadelphia: I recall a patient operated on in 1889 for large giant-cell sarcoma of the lower jaw by free chiseling and curettement but without removal of the maxilla. The patient lived for more than ten years after this operation, and may be alive today.

Dr. Joseph A. Blake, New York: I had a case of sarcoma of the fourth finger. A simple operation in this case proved most satisfactory, and now, three years since operation, there is a normal phalanx.

Dr. Harry M. Sherman, San Francisco: In my experience salt solution poured into these cavities a little in excess just before the last stitches are taken is as good as any other material for filling; it is replaced by blood and obviates the necessity of putting in any foreign body.

Dr. Dudley P. Allen, Cleveland: Some years ago, I removed the lower jaw of a patient for giant-cell sarcoma, leaving but a small portion of the substance of the jaw. I used a splint to hold the teeth in place. The patient recovered entirely and is now well.

Dr. William S. Halsted, Baltimore: In a case of myxoma of the humerus, although the disease involved the bone from one end to the other, there was no cyst and no fibrous tissue. The bone was excised four years ago except for a strip posteriorly and at the lower end, and the entire cavity carefully swabbed out with phenol. The patient made a good recovery and had a strong humerus, but there were implantation recurrences in the soft parts on two occasions. The patient is now perfectly well.

Dr. Nathan Jacobson, Syracuse: I recall a patient with giant-cell sarcoma of the jaw in whom I did a partial excision of the upper jaw about 25 years ago. The patient is still living. There was never any recurrence. In my experience in those cases of giant-cell sarcoma in which there is reasonable cleaning out there is seldom a recurrence of the growth.

Professor A. Von Eiselsberg, Vienna: In such cases as these mentioned, in Vienna we are in the habit, before finishing the operation, of pouring boiling water into the wound in order to destroy all the germs, and have found it a most satisfactory method.

Dr. J. Bloodgood: Dr. Halsted's case of exostosis with involvement of the humerus brings out the point that pure myxoma is a benign tumor; recurrence after operation may be due not so much to leaving a portion of the tumor growth behind as to infecting the wound in removal of the tumor. In such cases it would be well to use boiling water, pure phenol, or the Paquelin cautery to disinfect the wound.

Diagnosis and Surgical Treatment of Esophageal Diverticula

Dr. C. H. Mayo, Rochester, Minn.: Most cases of esophageal diverticula are pharyngo-esophageal. The condition is confined to adults. Dysphagia is the most common symptom; cough and dyspnea are common. Distended sacs are often visible in the neck and can be emptied by pressure. The condition is disclosed by probing and by radiograph of the bismuth-distended sac. H. S. Plummer's method of diagnosis is a combination of the technic of Mixter and Dunham, as used in stricture. The patient swallows a silk thread which passes into the intestine. The Plummer perforated acorn probe passed on the thread gives the depth of the pocket and location of its neck. Gastrostomy for temporary feeding may be necessary. Operation is by lateral oblique incision; blunt dissection; exposure of sac and excision; closure by suture; rubber tissue drain.

Thoracic Surgery on Human Beings

Dr. Willy Meyer, New York: I have operated on 10 patients with the help of my differential pressure apparatus. In two young patients, 6 and 11 years old respectively, who had suffered for years from bronchiectatic abscess symptoms, and were bad risks, I extirpated a lobe of the lung in each case, but neither recovered. Three times exploratory thoracotomy was done for cancer of the esophagus with recovery. In order to do good surgical work when operating for a malignant stricture of the esophagus I have found it necessary to get the scapula out of the way and, therefore, propose as a preliminary operation the Schede-Friedrich flap operation, by which the entire shoulder girdle is turned up, thus permitting the surgeon to make his incision into the thoracic cavity wherever required; often two incisions are necessary. On March 31, 1910, I proceeded in this way for a cancer of the esophagus in a patient aged 43. It was found that the malignant tumor extended from about 1½ inches above the cardia to the aortic arch. After division of the esophagus and inversion of the lower stump through the sixth intercostal space, the third interspace was opened, and the healthy portion of esophagus reached, outside of the common carotid artery, after proper division of the costal pleura; then the entire diseased portion was shelled out and brought in front of the aortic arch. To my dismay I found in the course of this latter part of the operation that the growth involved the right pneumogastric nerve; it was impossible to push the nerve off; it had to be divided at the lower end of the tumor, and again interfered with in amputating the esophagus above the upper border of the tumor. The proximal end was also inverted by a double purse-string suture, the intention being to do gastrostomy two or three days later. The interference with the pneumogastric nerve had a deleterious effect on the heart action, which up to this time had been splendid. The operation was well completed, but in spite of intravenous infusion given, the patient succumbed shortly afterward. The only hope of operative success in these cases lies in early operation, certainly before the intimately adjacent pneumogastric branches are involved, and the first step of such operation should be to free these nerves. Their involvement will more or less decide the operability or inoperability of the given case. Up to the present time resection of the esophagus has a mortality of 100 per cent.

End-to-End Intestinal Anastomosis by the Invagination Method

Dr. C. L. Gibson, New York: End-to-end intestinal anastomosis by telescoping one segment into the other has been practiced from time immemorial, but at present has no recognized position in surgery. My present technic, I believe, furnishes a method for which there is a demand, particularly in the surgery of the lower end of the colon. It is as follows: The upper cut edge of the gut is seized with two Kocher clamps and introduced by these into the lumen of the lower end and maintained there by an assistant. The extent to which it is feasible to accomplish this invagination will vary. The gut is rotated about a quarter circle so that the nonperiosteal covered surfaces do not entirely approximate in the circumference. From eight to twelve interrupted silk sutures are introduced thus: A Lembert suture is begun on the lower segment, the needle issuing just short of the cut edge, on the upper segment the needle is introduced just above the line where the cut edge of the lower segment lies against the intact wall of the upper. When the knot is tied the free cut edge has been turned inward, and only the peritoneal surfaces are in contact. A continuous running suture is applied over this area further invaginating the first ones, the Kocher clamps being previously withdrawn.

Postoperative Intestinal Obstruction

DR. GEORGE WOOLSEY, New York: Postoperative intestinal obstruction is either mechanical or paralytic. In early cases diagnosis is not so easy as it is obscured by peritonitis, operative trauma and the sequelæ of anesthesia. Many of the symptoms of obstruction and peritonitis are identical. Rigidity is the important sign of peritonitis and absolute constipation of obstruction. If the latter cannot be relieved, a diagnosis of obstruction should be made. The problem in prophylaxis is to prevent sepsis, operative trauma and adhesions, to which nearly all cases are due: hence operation is indicated in all cases of appendicitis as soon as diagnosis is made. When septic peritonitis is present modern technic (Murphy's) will cure in most cases and prevent paralytic ileus. To prevent atony rough and undue handling of intestines should be avoided. When early distention is marked and increasing, enemata of various kinds may be used with or without physostigmin. Stupes and lavage are also very useful. The prevention of adhesions is largely a matter of careful technic. Operate early, rapidly, yet carefully, and avoid drainage. If drains are necessary, the kind of drains and their position are of great importance. I remove source of infection, avoid displacing bowels, cover denuded peritoneum if possible, encourage early peristalsis and advise frequent change of position after operation. Treatment of actual obstructions is operative. In late obstructions, ample incision should be made over site of obstruction, if it is known, otherwise exploratory operation is indicated. Collapsed and distended coils are guides to obstruction. If gut is not viable I resect and anastomose. In early obstructions, palliation by enemata, physostigmin, lavage, etc., should not be persisted in too long. Most patients are operated on too late.

DISCUSSION

DR. CHARLES H. MAYO, Rochester, Minn.: I want to testify to the invagination method being a good one in the removal of tumors low in the sigmoid, at the upper rectum; in fact, it is about the only way one can get union.

DR. ALBERT J. OCHSNER, Chicago: If immediately on the appearance of nausea or gaseous distention gastric lavage be instituted, there will be fewer instances of intestinal obstruction following shortly after operation.

DR. E. WYLLYS ANDREWS, Chicago: End-to-end anastomosis implies for success that we get the lumen at once, and this is not true with the McGraw ligature; but if we can devise a method by which all the advantages of this ligature can be strengthened by obtaining the open lumen immediately we will have an ideal method.

DR. ALEXANDER H. FERGUSON, Chicago: In regard to operative obstruction and the prevention of adhesions following operations, I would say that for four years I have used subgallate of bismuth, smearing it over all raw surfaces, with most complete satisfaction.

Abnormal Position of the Duodenum

DR. G. E. ARMSTRONG, Montreal: The duodenum is singularly constant in its relations, course and length; any exceptions are exceedingly rare and worthy of note. In the anomaly reported, the duodenum ran to the right and then turned downward external to the hepatic flexure, ascending colon and cecum, and, merging into the jejunum, passed from without inward below the cecum into the small intestine area. The duodenum was completely surrounded by peritoneum. It had a long mesentery throughout and could easily be held two or three inches in front of the abdominal wall. The head of the pancreas, closely applied to the duodenum, was visible and palpable between the layers of the duodenal mesentery, and readily followed the duodenum when the latter was brought outside the body. There was no ligament of Treitz and no fossa duodeno-jejunalis. The condition is clearly one of arrested development. The cecum in this case did not mount upward to the lower hypochondrium and did not pass in front of the loop of the duodenum. The cecum did not descend to its usual final resting place in the right iliac fossa. It was high, completely surrounded by peritoneum, very movable, and could be brought out through the epigastric incision and held eight inches in front of the body.

DISCUSSION

DR. MAURICE H. RICHARDSON, Boston: I have observed a case in which the appendix, the gall-bladder, the liver and the ileocecal valve were on the left side, the spleen on the right side, and the heart on the right side.

DR. EMMET RIXFORD, San Francisco: I would put on record a case of failure of rotation of the primary gut. The explanation of this condition is probably to be explained on the basis of adhesions of the cecum to the parietal peritoneum the result of a fetal peritonitis.

DR. LEONARD FREEMAN, Denver: I had a case in which acute dilatation of the stomach followed an unimportant pelvic operation, and which at autopsy showed the duodenum passing directly beneath the liver.

(To be continued)

AMERICAN ORTHOPEDIC ASSOCIATION

Annual Meeting, held in Washington, D. C., May 3-5, 1910

(Concluded from page 1996, Vol. LIV)

Officers Elected

The following officers were elected: President, Dr. Albert H. Freiberg, Cincinnati; vice-presidents, Drs. A. R. Shands, Washington and Robert B. Osgood, Boston; treasurer, Dr. G. G. Davis, Philadelphia; secretary, Dr. Ralph R. Fitch, Rochester, N. Y.

SYMPOSIUM ON SCOLIOSIS

Treatment of Structural Scoliosis

DR. WALTER TRUSLOW, Brooklyn: In my opinion the embarrassing and health-depleting conditions of the severely scoliotic patient should be vigorously attacked. I do not consider either prolonged rest or vigorous gymnastic treatment adequate to overcome structural changes. There is considerable room for improvement in methods of treating these cases, and an analysis of the deformity into its component elements, with regard to the degree of each, would lead to a better understanding of the cases in hand, and would point out the method of correction to be used. Frequently changed plaster-of-Paris jackets with large windows are employed because of their cheapness and the adaptability of the material.

Apparatus for the Treatment of Scoliosis During Sleep

PROF. FRITZ LANGE exhibited a brace that he had devised for this purpose, thus preventing patients from losing at night all the good that they have acquired in the day time.

DISCUSSION

DR. R. H. SAYRE, New York: Patients who are badly deformed cannot be cured, but a great deal can be done to ameliorate the condition of such patients. In a good many cases we do not exert our force as we should. We do not exert a rotating force to the vertebræ. The result of applying the pad in Professor Lange's apparatus and in Dr. Truslow's method of treatment is to cause a lateral, instead of a rotating pressure. Dr. Lange is right in saying that to correct the spine for six hours and leave it to get crooked sixteen hours during the night is useless. If we stop the brace at the axilla we leave the upper part of the body very much unprotected. I believe that not enough stress has been laid on preventing cases from becoming scoliotic from anterior poliomyelitis in which the thorax is involved, by means of traction on the head for a long time.

DR. A. H. FREIBURG, Cincinnati, showed an apparatus for measuring scoliosis. It combines in one instrument the work formerly performed by two imported instruments, and is cheaper for Americans to obtain.

Dr. Truslow, Brooklyn: I was very much pleased to hear that Dr. Lange appreciates the necessity for the fixation treatment in scoliosis. It seems as if the tendency were certainly toward that method of treatment.

SYMPOSIUM ON POLIOMYELITIS

The Relation of Poliomyelitis to the Community with Reference to Etiology and Prevention

Dr. Robert W. Lovett, Boston, read an exhaustive paper on this subject, illustrated with charts containing statistics gathered from the Massachusetts epidemic that occurred last year. The following facts were mentioned:

Outbreaks of infantile paralysis have greatly increased in various parts of the world within the last five years, in a measure not to be explained in any way by the increased interest in the disease. It is apparently more prevalent in warm than in cold countries. From the northern part of the United States more cases have been reported than from other parts of the world. We no not know by what channel the disease enters the body, nor how to prevent its spread. Careful investigations have been made, including a house to house canvass in infected districts, made by competent medical men, giving their whole time to the investigation.

The Clinical Aspects of Poliomyelitis: Types; Communicability; Mortality

Dr. L. Emmet Holt, New York: The disease varies greatly in its communicability at different times, and these differences cannot yet be reconciled. It often demands strict quarantine. Healthy persons may be carriers of infection, which may occur at a considerable time after contact with active cases. There is no evidence of the existence of any other medium of contagion than contact with persons suffering with the disease or those exposed to it. A new name for the disease should be sought, and I suggest the term epidemic myelitis or epidemic myelo-encephalitis.

Experimental Epidemic Poliomyelitis and Its Relation to Human Beings

Dr. Simon Flexner, New York, presented a report on the experimental study of poliomyelitis in monkeys, giving facts relating to the spontaneous disease in man, covering the work recently reported in The Journal.

Paralysis of the Neck and Diaphragm in Poliomyelitis

Dr. Irving M. Snow, Buffalo: Neck paralysis in combination with loss of power in the extremities is not unusual in poliomyelitis, but isolated neck paralysis is extremely rare. Paralysis of the diaphragm is scarcely mentioned in treatises on poliomyelitis, except in connection with the fatal type of Landry's paralysis. From my study of the literature on the subject, the following conclusions may be drawn: 1. Poliomyelitis affecting the origins of the phrenic and spinal accessory nerves is rare, but in the two reported cases recovery occurred. 2. Paralysis of the neck muscles occurs occasionally in epidemic poliomyelitis and severe Landry's paralysis. The prognosis is favorable as to restoration of function; some improvement always takes place. 3. Paralysis of the diaphragm is exceptionally seen in poliomyelitis; and although this is dangerous, recovery is possible.

Pathology of Poliomyelitis

Dr. Israel Strauss, New York: The rapid disappearance of the extensive paralysis often present, even in sporadic cases of poliomyelitis, is probably due to a subsidence of the inflammatory edema that has interfered with the conductivity of the nerve-fibers, a similar condition being found in the collateral edema causing paraplegia in Pott's disease. Many of the cells at any particular level of the cord are either not at all or very slightly affected and probably undergo a rapid restoration of function. Sporadic cases rarely have symptoms referable to the meninges, probably because the virus is not virulent enough to cause the final infiltration of the fatal cases. The extent of the paralysis gives no idea of the extent of the lesion. The bulbar cases may have cord involvement, and yet no symptoms of it. In every case in which the cord is affected, there are some inflammatory changes in the bulb, even though no symptoms are present, as even in those cases in which death is due to respiratory failure an examination of the bulb shows an increasingly intense inflammation extending up into the basal ganglia, and yet causing no other symptoms than paralysis of the motor nucleus of the nasal and glosso-pharyngeal nerves. In the vast majority of cases the physician is handicapped by his inability to recognize the disease.

The Treatment of Poliomyelitis

Prof. Fritz Lange, Munich: In the early stage of the disease one should try to prevent the extension of the seat of the infection into the spinal column, and holding the affected organ still is a most important requirement for speedy recovery. After the acute stage has passed a second task devolves on the orthopedist, to assist the restoration of the paralyzed muscles and prevent the occurrence of contractions. The nourishment of the affected muscles by the blood can be favored by the application of stimulation; but I warn physicians against the use of rough, hard massage, or of hard apparatus. Most patients are content with the relief afforded by the use of apparatus, and will not submit to operation; but I have seen undoubted success obtained by operative treatment. Patients are often troubled by stiffness of the foot in walking over irregular ground, and I therefore sought an operation that would retain the movements of the foot to 90 degrees, and only restrain the dangerous sinking of the foot beyond this point. In performing this operation artificial ligaments of silk were used and I think the results will be good. Transplantation of the tendon takes the place of arthrodesis.

The chief advantages of the operation are that, with careful after-treatment, the patients are able to walk without apparatus or danger of relapse, and with normal function of the transplanted muscle. The profession will soon learn to distinguish better between the indications for arthrodesis and those for transplantation of tendons. The latter operation, having already brought benefit to countless patients, may be considered among the greatest advances in orthopedic surgery.

DISCUSSION

Dr. Bernard Sachs, New York: Although the pathological conditions show that there is much more than a mere anterior poliomyelitis in the disease called by this name, I think it is well to retain that designation, which is so well known, as the lesion is largely in the gray matter. In the treatment of these cases of infantile spinal paralysis I believe the time given to massage and electricity to be practically wasted. I will not say that this method of treatment does harm, but in my experience I cannot put my finger on any definite good done by it. I believe that more good will be done by the early institution of orthopedic measures. I trust that the bloodless and the bloody surgery will be applied to these cases; and the earlier the period, the better will be the results. The so-called atypical forms of poliomyelitis are so rare compared with the typical that we should not allow our conception of the disease to be disturbed by the occasional occurrence of atypical cases.

Dr. H. Winnett Orr, Lincoln, Neb.: I have been endeavoring to collect as much information as possible regarding the epidemic that recently occurred in Nebraska. There were over six hundred cases. I have records of 619, concerning two-thirds of which I have been able to obtain detailed information.

Muscle-Group Isolation and Nerve-Anastomosis in the Treatment of Paralyses of the Extremities

Dr. Nathaniel Allison and Dr. Sidney I. Schwab, St. Louis, considered briefly the position now occupied in the treatment of the paralyses of the extremities by peripheral nerve surgery as compared with that of muscle and tendon transference, and laid stress on the importance of tabulating cases of paralyses of the extremities in terms of nerves rather than in terms of muscles or deformities. Cases of athetosis and spasticity were treated by muscle-group isolation only; flaccid paralyses, by muscle-group isolation and nerve-anastonosis and cases with complicated tic movements, by induced paralysis. Illustrative cases of each of these groups were cited.

DISCUSSION

Dr. Sidney I. Schwab, St. Louis: The alcohol injections in spastic cases are not curative. All that we attempted was temporarily to throw out of action the antagonistic muscle. The opposing group is meanwhile exercised with massage; so that by the time the original nerve regenerates, the muscular force has been somewhat transferred to the opponent group. A great advantage, also, is that the patient can be up out of bed within a few days. There is no necessity for the wearing of a plaster cast. In the second group of cases the operation of throwing out of action the antagonistic pull was very effective. By the time the nerve regenerates, the antagonistic muscle has not regained its original force. The third class of cases, tics, can be attacked in a much better way than ever before by surgical treatment. In one case, while three nerves were alcoholized and thrown out of function, and there was complete anesthesia to touch and pain, no trophic disturbance appeared in any part of the arm.

Dr. B. E. McKenzie, Toronto: Will Dr. Allison tell us some particulars regarding the technic and the strength of the alcohol used in the injections?

Dr. G. G. Davis, Philadelphia: To my mind, the alcohol injection of nerves is similar to the division of nerves. After the nerves unite they resume their functions; and after the effects of the alcohol wear off they also resume their functions. If they do not resume their functions absolutely after alcoholization, there is an advance over division; but I do not think that we have had sufficient results shown yet to demonstrate that regeneration of the nerve does not take place entirely, or to what extent it fails to return. In regard to treatment by means of nerve anastomosis, I think that we must wait longer before we can determine the value of that method of treatment.

Dr. Virgil P. Gibney, New York: If these gentlemen can, by attacking the nerves, destroy them for a number of months, they can develop the opposing muscles during that time; and this cannot be done with the use of plaster of Paris. If the children are going around, their education can be carried on; so it seems a wonderful advance in the therapeutics of spastic paralysis.

Dr. Walter G. Stern, Cleveland, O.: Whatever operation you do for athetosis, the movements return after awhile. Amputate the arm below the shoulder and the shoulder will move.

Dr. N. Allison, St. Louis: We varied the strength of the alcohol to a certain extent. It must be 50 per cent. to have any effect. Some patients had more lasting paralyses than others. I think that the percentage of alcohol may have something to do with this. I have used straight alcohol in some cases.

VACCINE THERAPY

The Indications for and the Uses of Vaccine Therapy in Orthopedic Diseases

Dr. Charles F. Painter, Boston: There is no well-established theoretical ground for the belief that, in gonorrheal and tuberculous joint infections vaccines can play a curative rôle. Very little progress has been made as regards either the diagnosis or treatment of chronic non-tuberculous infections. The complement-binding reaction in the diagnosis of syphilitic bone and joint infections has stood the test of practical experience very well. There is reason for thinking that the future treatment of these conditions will be much facilitated by vaccine and serum therapy, although the results of this are not yet even comparable to those obtained from the use of Marmorek's serum in the treatment of tuberculous arthritis. The efforts of the members of the association should be directed to the perfection of methods of putting into practice a test for which there seems to be so much theoretical and experimental justification; but statistics, however favorable, are undesirable, unless there is indisputable ground for the claim that the results recorded can be obtained under no other form of treatment.

Investigations as to the Value of Tuberculin in the Treatment of Tuberculous Joint Disease at the Home for Destitute Crippled Children at Chicago

Dr. John Ridlon, Chicago, gave the details of these investigations, which were first by Wright's opsonic method and later by the so-called clinical method. His conclusions were that tuberculin administered by the clinical method in harmless doses was useless; and that in larger doses it was both dangerous and harmful.

DISCUSSION

Dr. V. P. Gibney, New York: May I present an optimistic report? During the past winter my staff used streptococcus and staphylococcus serum in cases of tuberculous sinus, but have not used tuberculin. In half a dozen of these cases the sinus has been permanently closed. I quite agree with Dr. Painter that these patients do improve at first under almost any form of treatment.

Dr. J. K. Young, Philadelphia: We have had very good results in Philadelphia in treating tuberculous sinuses by means of autogenous serums. It is important to use the autogenous method and the opsonic index, and not to employ the clinical method.

Dr. A. H. Freiberg, Cincinnati: Tuberculin is not the toxin of the tubercle bacillus, but a means of calling forth in the body the production of an increased amount of this toxin. In order to cure tuberculosis by the vaccine method we should have to use the toxin of the tubercle bacillus. At the same time tuberculin is entitled to a fair test. Evidence is pretty conclusive that in joint tuberculosis it is the bovine form of the tubercle bacillus that is present. If that is true we should use bovine and not human tuberculin in these cases. I have had excellent results from the use of Marmorek's serum, the only difficulty being that it is hard to get and very expensive.

Dr. Clarence L. Starr, Toronto: In Toronto we have dropped the use of tuberculin in joint or sinus cases, because we obtained no results from its use. The opsonic index is absolutely useless, as it varies materially in children as the result of autointoxication. In mixed infections we have adopted the use of staphylococcus, and occasionally streptococcus serum, with sufficiently good results to warrant us in continuing their use. We have equally good success, whether we use stock vaccine or vaccine prepared from the patient himself.

Dr. S. J. Hunkin, San Francisco: It seems to me that the results obtained by the use of vaccines in the treatment of bone tuberculosis depend purely on the temperament of the man employing them.

Dr. Charles F. Painter, Boston: I purposely said nothing about mixed infections, but I believe that the only satisfactory results have been obtained in that sort of cases.

Further Observations on the Pathology of Joint Tuberculosis, and Practical Deductions Therefrom

Dr. Leonard W. Ely, New York: Only two elements of joints are subject to tuberculosis: the synovial membrane and the red marrow of the bone as shown in the specimens of tuberculous joints here exhibited. In the sixty cases from which these specimens were taken, there were thirty-five errors in diagnosis. Tuberculosis might exist in one spot in a joint and not in another, repair and invasion going on simultaneously in different parts of the same joint. The way to cure the process is to deprive the joint temporarily of motion, but this is seldom successful in adults. In adults, therefore, it is necessary to deprive the joint of motion permanently. The presence of bone marrow and of synovia depends on their function; and when function is stopped they disappear. The disease, having nothing on which to feed, disappears also.

DISCUSSION

Dr. J. K. Young, Philadelphia: The occurrence of syphilis preceding tuberculosis in the same individual is interesting, because I have seen tuberculosis in individuals who previously suffered from syphilis.

Dr. M. M. Shaffer, New York: I should like to know whether the initial lesion is in the synovial membrane or the bone marrow.

Dr. Fred H. Albee, New York: It has been noted in my observations that it is not necessary to remove all the infected tissue from the knee joint in order to obtain a good result.

Dr. Wallace Blanchard, Chicago: I have been surprised at the number of cases of old resected knee joint that have come to me with a history of having been healed for two or three years, and afterwards developing sinuses. I question very much whether excision of the knee joint modifies the progress of the disease except temporarily; and it more than quadruples the deformity.

Dr. G. G. Davis, Philadelphia: Would Dr. Ely, as soon as practicable after he has made a diagnosis of a distinct case of synovial tuberculosis in an adult, proceed to resection—that is to say, such resection as he does, which, as I understand it, is nothing more than an arthrodesis in which he takes off the cartilage in order to get immobility?

Dr. R. R. Fitch, Rochester, N. Y.: I think that Dr. Ely would accomplish the doing away with function more quickly, if he would put on a bone plate, or sink screws and apply strong wires, for the purpose of obtaining bony apposition.

Dr. L. W. Ely, New York: Dr. Young did not understand me aright. At first I thought it a case of syphilis, and then one of osteomyelitis; it turned out to be tuberculosis. Regarding the origin of the disease, I think that in adults it is equally common for it to start in the synovia and in the bone. If it starts in one, it may never involve the other; but the general rule is that after it starts in one it involves the other before long. I cannot diagnose the synovial from the bony type, but I can make a fairly good guess at it. I think that the synovial disease is characterized by less atrophy, milder symptoms, less tendency to deformity, and a slower course. When I diagnose synovial tuberculosis I tell the patient that I will recommend that he have his joint put up in plaster for six months, in case of a mistake in the diagnosis; and that at the end of that time I shall probably have to resect the joint. Bone plates are not necessary. Usually the two ends of the joint lock tightly together, and there is no tendency to mobility.

Osteochondritis Desiccans

Drs. Albert H. Freiberg and Paul G. Woolley, Cincinnati: Koenig has maintained the existence of osteochondritis as a distinct entity and as the cause of joint mice, excepting those produced by arthritis deformans. [They reported a case in which operation and pathological investigation furnished corroboration of Koenig's views, but in which certain new aspects were added.] The great interest in our case lies in the fact that three varieties of joint changes were found going on in one joint at the same time, apparently depending in their reciprocal relation on the vascular changes. We do not think that the types of chronic deforming joint affections can be looked on as separate and distinct diseases. The future will disclose the etiological factors that determine the prevalence of this or that type in a give case.

DISCUSSION

Dr. C. F. Painter, Boston: It does not seem to me that these *x*-rays are suggestive of the appearances in the ordinary cases of chronic hypertrophic osteoarthritis. The explanation may be that these appearances were the result of the vascular changes present at the same time.

Dr. Woolley, Cincinnati: I do not think that we have proved anything by the small amount of work we have done, but I do think we have some basis for supporting the work of Wollenberg. It was interesting that we could get these various changes in one case—changes that appeared like those described by other men in various forms of atrophic and hypertrophic joint disease.

Dr. A. H. Freiberg, Cincinnati: I did not mean to convey the impression that these appearances were like those we see usually in radiograms of hypertrophic arthritis. The interest lay in the fact that we had a case in which free bodies had formed, and were apparently still forming; and in which a second kind of free bodies had apparently formed on other occasions. When we came to examine the changed synovial membrane of these joints, we found changes in accord with the changes described by Wollenberg in cases that were typical of hypertrophic arthritis; and it seemed to us that these two things must be brought into correlation, and that some explanation of this character is to be found for these cases in the *osteochondritis desiccans* of Koenig.

Syphilis of the Bones and Its Bearing on Hypertrophy and Atrophy

Dr. S. L. McCurdy, Pittsburg: Syphilis is a factor in the majority of cases of bone disease of all varieties. Hypertrophies and atrophies should have a reclassification, with the causative factor as the basis, rather than the pathological end. In tuberculous disease of the bones the bones are always atrophied; while in syphilitic bone disease they are always hypertrophied and also eburnated, with exostoses. There is always a spindle enlargement, and not only a hyperostosis, but an endostosis. Charcot's disease is in many instances syphilitic, because it melts away under constitutional treatment. Saber-tibia I also consider to be always syphilitic. The objects of operation in syphilitic bone disease are to liberate pus, to relieve pain, and to remove sequestra. One should excise but never destroy tissue. I approve of the use of iodid of potash, but not of mercurial inunctions, and mechanical treatment should be employed just as in ordinary tuberculous bone disease.

DISCUSSION

Dr. Leonard W. Ely, New York: While I believe that syphilitic bone disease in cases diagnosed as tuberculosis has existed, I think it is comparatively rare. The statement that the lesions of tuberculosis are always atrophic is also an error, nor is the therapeutic test decisive.

Dr. S. L. McCurdy, Pittsburg: I did not expect very many to agree with me. I think that these statistics that I have been collecting for a number of years are sufficient ground for me to continue my plan of treatment, because I have usually cut short the course of the disease by employing iodid of potash.

Coxa Vara

Dr. Wallace Blanchard, Chicago: The two cases of sadly deforming coxa vara here reported may help to clear up some questions of differential diagnosis. I object to the statement that coxa vara is due to tuberculosis, as I have found rachitic coxa vara greatly in excess of all other types. This might, however, be due to my special line of work, the correction of knock-knees. Treatment of the deformity during its progress is very unsatisfactory; but when the disease has run its course, osteotomy for the elevation of the head of the femur and for the relief of the adduction deformity gives good results.

DISCUSSION

Dr. G. G. Davis, Philadelphia: I would suggest that the first case was analogous to cases of subluxation of the wrist, which occur in adolescents and young adults, and in which the wrist is distorted, especially the lower end of the radius. This disease is probably due to rickets.

Juxta-Epiphyseal Fractures of Hip and Shoulder

Dr. Fred H. Albee, New York discussed the diagnosis and the frequency of occurrence of juxta-epiphyseal fracture of the upper end of the humerus and femur, and said that faulty diagnoses are frequent. He took into consideration the different elements displacing the fragments, and laid stress on the importance of the use of position in fixing the long, or controllable, fragment in alignment with the short, or uncontrollable, fragment. Several illustrative cases were cited.

DISCUSSION

Dr. H. Winnett Orr, Lincoln, Neb.: The tracing of one of Dr. Albee's cases might have been taken for the plate of one of my patients. I immediately placed this boy in the sort of plaster dressing described by Dr. Albee, but took the liberty of extending it a short distance farther, so as to include the hand.

Dr. Frank R. Peckham, Providence, R. I.: It should be recognized by the profession that these fractures should be treated by orthopedists rather than by general surgeons. Regarding fractured neck of the femur, if you put every such fracture in extreme abduction, you will not always have the fragments in perfect apposition. The correct angle should be determined by the *x*-ray. Dr. Albee has demonstrated the application of the same principle to fractures of the upper extremity. When these fractures are treated in bed you can begin passive motion and massage early. Then, when you have union, you have the functional result also.

Dr. S. J. Hunkin, San Francisco: My experience has shown that not in every case can the fragments be held in apposition in a position of extreme abduction; and in two or three instances I have found it absolutely impossible to hold them in apposition, regardless of any position that was taken by the leg. It is also sometimes impossible to tell whether the fragments are in apposition or not, even by means of the *x*-ray. I think that practically all fractures of the femur should be cut down on. The fragments should then be found to be replaced by the finger and eye, and fastened with some metallic suture. The splint used at first should be one that will allow you to see the part.

Dr. Albee, New York: I want to emphasize the difficulty of holding the epiphyseal fragments of the humerus. An epiphyseal fracture is held much more firmly by this method than is one of the neck, although it will usually hold the latter.

SYMPOSIUM ON THE FOOT

Relaxation of the Annular Ligament of the Ankle-Joint as a Cause for Weak Foot and Flat-Foot

Dr. J. Torrance Rugh, Philadelphia: I have for some years been inclined to believe that the cause of weak feet and flat-feet lies in the lower portion of the annular ligament, which performs three distinct functions in the economy of the foot. It binds down the tendons of the tibialis anticus and the extensor proprius hallucis, and keeps them tense; it acts as a sling for the support of the dorsalis; and it takes up the slack in the plantar fascia, when the tibialis anticus and the dorsal flexor of the great toe contract. It, therefore, not only has important functions of its own, but it also assists the neighboring structures in the performance of their functions; and if they become relaxed, the strain on this portion of the ligament increases, and it may give way. For this reason, it should be considered in cases of weak or flat foot.

Osteophytes of the Os Calcis

Dr. J. D. Griffith, Kansas City, Mo.: Bacteria are not necessary to the production of a deposit of bone by the periosteum, but constant irritation and pressure may easily inaugurate a *locus minoris resistentiæ* and cause osteoblastic deposition, especially when perverted metabolism is added. This thickened condition or deposition of extra bone is frequently the cause of painful feet. The horseshoe incision is the only one that is entirely satisfactory and devoid of the possibility of causing future trouble.

An Operation for the Relief of Anterior Metatarsalgia, Including Morton's Disease

Dr. A. Mackenzie Forbes, Montreal: This condition is primarily due to abnormal laxity of the ligaments and the transverse metatarsus muscle, allowing the falling of one or more metatarsal heads. The pressure of the displaced bone on the soft tissues beneath it is the cause of the pain, which may later become exaggerated by the formation of a callus on the weight-bearing skin. Secondarily, a mild form of arthritis sometimes supervenes. As the second, third and fourth metatarso-phalangeal joints are supplied by the external branches of the anterior tibial, which motor nerve supplies the extensor longus digitorum, spasm of this muscle often results, causing hyperextension of the phalanges of the affected joints. When chronic, this hyperextensison is often followed by a dorsal subluxation of the phalanx; and this tends to depress the heads of the affected metatarsals against the adjacent soft tissues. The only difficulties in the operation proposed for the relief of this condition are those connected with the attachment of the extensor tendon to the depressed heads and the guarding against a low form of infection, which may destroy the attachment. The first difficulty is overcome by raising the head by direct pressure from below.

Problems in the Treatment of Club-Foot

Dr. W. G. Stern, Cleveland, Ohio: When not due to faulty technic in applying the plaster cast, a decubitus occurring on the dorsum of the foot is due to cutting off the arterial supply of the arch afflicted; and the cyanosis of the toes is due to a damming back of the venous return. Both of these untoward occurrences are caused by the compression of the soft tissues of the dorsum from over-correction. The relief of this condition may be brought about by reducing the over-correction and fixing the foot in a less extreme position. The amount of correction practicable at any one sitting is primarily dependent on the circulation, and is often considerably less than the maximum. For the best results in club-foot, a maximum over-correction must be secured; but this should not be done at one sitting. The circulation in this, as in other forcible operations, should control the amount of correction obtainable at any one sitting; and if the latter is not sufficient for a permanent cure, the correction must be repeated at suitable intervals until the maximum over-correction can be safely maintained.

Flat-Foot. Mid-Tarsal Valgus

Dr. E. H. Bradford, Boston: The foot changes shape under different static conditions, and there is difficulty in checking the inward sag and twist. After operation in order to regain suppleness and strength, daily exercise is a necessity. It is important to correct joint stiffening and restore muscular strength. Supports are beneficial but not curative.

DISCUSSION

Dr. H. P. H. Galloway, Winnipeg: I have used Dr. Griffith's incision with more satisfaction than the simple linear incision. I never employ the latter on the center of the heel. The operation described by Dr. Forbes is an exceedingly ingenious application of an operation employed by all of us for other conditions. I have frequently transplanted the extensor tendons of the toes to overcome the closed condition of the toes met with in static paralysis, and to secure more power of dorsal flexion by transplanting these tendons from a very movable to a fixed point. I have devised a simple instrument that automatically centers the drill in making holes in bones of very small diameter. There is then no possibility of the drill's slipping. I have always succeeded in relieving metatarsalgia by mechanical means. If I find a case that I cannot relieve in this way, I will adopt this operation.

Dr. G. G. Davis, Philadelphia: I should like to call attention to resection of the head of the metatarsal bone for metatarsalgia. Morton did this, and not infrequently found that it destroyed the stability of the toe. Later, he often performed amputation of the toe. Therefore, it would be interesting to know whether in Dr. Forbe's procedure the tendon of the extensor brevis is sufficient to maintain the toe in a straight line.

Dr. S. L. McCurdy, Pittsburg: I want to speak of a method that I have used when the tendons are taken from the foot. I take from the toes tendons long enough to wrap entirely around the foot in cases of closed toe. They are brought back and sutured to themselves. This gives a perfectly stable anchorage.

Dr. Young: I have had occasion to perform the Morton operation several times, and have always had to remove the toe. The statement has been made that it is not necessary to operate on these cases. As a man's experience increases, he will find that some of these cases will require operation; and that of Morton is perfectly satisfactory.

Book Notices

Preparatory and After Treatment in Operative Cases. By Herman A. Haubold, M.D., Clinical Professor in Surgery and Demonstrator of Operative Surgery, New York University and Bellevue Hospital Medical College, New York. Cloth. Price, $6. Pp. 650, with 429 illustrations. New York: D. Appleton & Co., 1910.

The author intends his book to furnish a source "from which the practitioner can draw information with regard to the handling of a patient to be operated on from the time the decision to operate is reached up to the making of the incision," taking up the case again from the time the operative technic is ended until recovery is complete.

The unjust relations which often obtain between the surgeon and the man who sends him the case are deplored, conditions which have resulted in loss of the family to the practitioner, or to a division of fees. To the end that these conditions may be improved, the author very commendably would educate the general practitioner in surgical technic, make him a closer ally of the surgeon and keep him in closer touch with his patient. There will, however, be some hesitancy on the part of surgeons to assume the responsibility for some one who has not the knowledge nor the experience to manage properly the preparation and after-care.

Where the operating is done in the country or in private homes, it is conceivable that a book of this kind can be invaluable to both practitioner and surgeon. For this purpose, however, the author covers too wide a field, going into operative technic and other details which are beyond the subject, according to his introductory declaration. Why should there be thirty pages descriptive of a hospital operating-room? Why should so much space be devoted to the suturing of wounds? As for catgut, the busy practitioner would scarcely be in a position to prepare catgut of sufficient reliability to recommend itself to the average surgeon. The author might have sacrificed some of the detail, and emphasized the great fundamental principles involved in surgery, preparatory and postoperative. He gives in detail the preparation of the patient, the instruments, dressing and suture material. Then follow chapters on the suturing, drainage and dressing of operative wounds. The methods are well illustrated and follow the newest technic. The treatment of postoperative vomiting, thirst and pain and the important question of feeding are admirably handled.

A discussion follows of operations in different regions, namely, head, neck, thorax, abdomen and extremities; also the pelvic and genitourinary organs. There is a good chapter on artificial limbs.

This book is more than a guide for the general practitioner; it contains much valuable information for the surgical assistant, and even for the surgeon himself. The text is carefully written and illustrated profusely with many original photographs. The mechanical side has been very well taken care of by the publishers.

Appleton's New Practical Cyclopedia. Edited by Marcus Benjamin, Ph.D., Editor of the United States National Museum, Washington, D. C., assisted by Arthur E. Bostwick, Librarian of the St. Louis Public Library; Gerald Van Casteel, Chief of Editorial Staff; George J. Hager, Expert Compiler and Statistician, with an Introduction by Elmer E. Brown, Ph.D., United States Commissioner of Education. In Six Volumes. Cloth. Price, $18 the set. Pp. 3000 (about). New York: D Appleton & Co., 1910.

In the introduction Commissioner Brown says: "It is one province of works of reference to supply, to a reasonable degree, the definite and elementary information which will enable any ordinary reader to make good his individual lack of knowledge on any subject of ordinary discussion." An examination of this work in six volumes, as compared with the "Universal Cyclopedia" of the same publishers in twelve volumes, shows that this decrease in volume has been secured by leaving out many subjects contained in the longer work and by condensation and abbreviations of others. The publishers say that an attempt has been made to give the descriptions of technical things in language that may be easily understood by any one. The work is, of course, intended for those who cannot afford to own and have not access to the larger and more exhaustive works of general reference, and should be judged on that basis. While condensation has been carried to a degree which will strike one familiar with the larger encyclopedias as excessive, this work will be useful to those who need more frequently to find some particular item of information than to find exhaustive information on some broad subject. Its plan of arrangement makes it easy of consultation. The index with analytical cross-references, and the group, or synthetical, index, are good features.

The book is mechanically well executed. The illustrations are for the most part identical with those used since cyclopedias were first made, but in addition there are some halftone photographic reproductions and a number of admirable colored plates.

Remedial Gymnastics for Heart Affections used at Bad-Nauheim. By Dr. Med. J. Hofmann and Dr. Med. L. Pohlman. Translated by John G. Garson, M.D., Edinburgh, Physician to Sanatoria and Bad-Nauheim, Eversley, Hants. Cloth. Price, 5 shillings. Pp. 128, with 42 illustrations. London: Swan Sonnenschein & Co., 1909.

The authors briefly refer to other systems of gymnastics used in heart diseases, but do not discuss them. The second chapter, which is one of the most important in the book, is a reprint of an article by Professor von Romberg, and tersely but fully describes the indications for and against the use of gymnastics in these affections. The succeeding chapters relate to methods of estimating the effect of gymnastics on the heart. The authors urge that no one method be relied on fully, for no single one will afford the needed information in every case. The effect on the pulse and the inferences to be adduced are first considered; then the effect of gymnastics on blood-pressure and on the size and shape of the heart, as shown by auscultation, percussion and *x*-ray, are discussed. Sommer's analysis of movements is highly commended as a means of determining fatigue of the heart muscle. This is a mechanical contrivance which registers on a moving paper tremors in all directions of a leg held horizontally without support. The various ways in which gymnastics can be used and their order are next considered. Nearly one half of the volume is devoted to illustrations and brief descriptions of the movements which constitute the Nauheim exercises.

This book is a commendable exposition of the Schott exercises used at Nauheim.

Studies in Immunity. By Professor Paul Ehrlich, Privy Councilor and Director of the Royal Institute for Experimental Therapy, Frankfurt, Germany, and his Collaborators. Collected and Translated by Charles Bolduan, M.D., Bacteriologist, Research Laboratory, *Department of Health, City of New York. Second Edition. Cloth.* Price, $6. Pp. 712. New York: John Wiley & Sons, 1910.

It reflects no little credit on the condition of medical science in America that so technical a work as this translation of the collected papers of Ehrlich and his collaborators has exhausted the first edition in less than four years. The translator has taken advantage of the opportunity, in this second edition, to add eight of the more recent papers, on the following topics: "The Multiplicity of Antibodies Occurring in Normal Serum," "The Binding of Hemolytic Amboceptors," "The Joint Action of Normal and Immune Amboceptors in Hemolysis," "The Power of Normal Serum to Deflect Complement," "The Joint Action of Several Amboceptors in Hemolysis," "Studies in Amboceptors," "Dissociation Phenomena in the Toxin-Antitoxin Combination," and "The Partial Function of Cells," the last being Ehrlich's Nobel Prize lecture. The absence of an index constituted a defect of the first edition which has been remedied in the second, and this will add much to the usefulness of the work. American medicine is much indebted to Dr. Bolduan for his service in rendering these masterpieces accessible to a larger audience than they could reach in their original vehicle.

Twenty-Eighth Annual Report of the State Department of Health of New York. For the Year Ending Dec. 31, 1907. Volume II, *Report of the Sanitary Engineering Division.* Cloth. Pp. 869, with illustrations. 1908.

The second volume of the twenty-eighth annual report of the New York State Board of Health contains the report of the chief engineer, Theodore Horton, on sewerage and sewage disposal of the towns of the state, giving diagrams, illustrations and explanations of a large number of plants for sewage disposal. He shows that a great many towns of the state are adopting modern methods of treatment by settling-tanks, septic tanks and filter or contact beds. The reports on the preservation of public water-supplies, the investigation of stream pollution and watersheds and the sanitary inspections of summer resorts, with the report to Governor Hughes of investigations ordered by him on the pollution of the upper Hudson and other streams, all go to show that New York has good laws and is well in advance in sanitary matters involving engineering problems. The report should be a valuable one to sanitarians and health boards as showing the method of handling the numerous difficult problems that come up in questions of state-wide sanitation.

[illegible] CIPLES OF METHODS OF ANALYTICAL CHEMISTRY [illegible] REACTIONS. By M. G. Chesneau, Ingénieur [illegible] Authorized Translation by Azariah T. Lincoln, Ph.D., Assistant Professor of Chemistry, Rensselaer Polytechnic Institute, and David H. Carnahan, Ph.D., Associate Professor of Romance Languages, University of Illinois. Cloth. Price, $1.75 net. Pp. 184. New York: The Macmillan Company, 1910.

The object of this work is not primarily to increase the number of methods of analytical procedure, but to increase the exactness of the methods now in use, by investigations in the light of recent physicochemical theories. The electrolytic or ionic theory appeared to the author to be in contradiction, in many cases, to facts, established by experiments; therefore another means of explanation was sought. The author discusses the chemistry of analytical reactions on the basis of calorific phenomena involved in the ordinary reactions and of the laws deduced from the principles of thermodynamics. From the nature of the theories employed it is not a handbook for the beginner but rather a book which can be employed only in very advanced work in theoretical lines.

Association News

PROCEEDINGS OF THE ST. LOUIS SESSION

(Continued from page 2090, Vol. LIV)

Section Transactions

Those who desire copies of the 1910 Transactions of any of the sections, but who are not on the permanent subscription list, should order them at once, as printing will commence soon on several. Only enough are printed to supply the demand, and each year some persons order too late to be supplied. Each volume is a cloth-bound book containing the articles and discussions in that particular section. A volume is issued for each section except the Section on Stomatology. When ordered in advance, each book costs the subscriber $1.00, payable at time of delivery.

It is to be remembered that one may give a permanent order for Transactions; and those specified are sent, from year to year, until the order is cancelled. Address orders to the American Medical Association, 535 Dearborn Avenue, Chicago.

Minutes of Sections

The minutes of the proceedings of the sections at the sixty-first annual session, held at St. Louis, June 7 to 10, 1910, are given below.

SECTION ON PRACTICE OF MEDICINE

TUESDAY, JUNE 7—AFTERNOON

The Section was called to order by the Chairman, Dr. George Blumer, New Haven, Conn., at 2 p. m., in the Third Baptist Church.

Dr. Max Einhorn, New York, read a paper on "Experiences with the Duodenal Contents in Man." No discussion.

Drs. Harvey G. Beck and William Royal Stokes, Baltimore, read a paper on: "A Case of Diffuse Ventriculo-Septal Myocarditis with Adams-Stokes' Syndrome."

Dr. Isaac I. Lemann, New Orleans, read a paper on "A Study of a Case of Heart-Block with Auricular Alternating Pulse." These two papers were discussed by Drs. Haven Emerson, New York, and Albert E. Taussig, St. Louis.

Dr. Seale Harris, Mobile, Ala., read a paper on "The Radical Cure of Malaria; Its Importance and How It May Be Attained." Discussed by Drs. Charles MacLellan, Chicago; Arnold Taubitz, Neelysville, Mo.; W. E. Chapman, Sheboygan, Mich.; I. J. Woelf, Kansas City, Mo.; Vernon Blythe, Paducah, Ky.; S. P. Child, Kansas City, Mo.; C. C. Bass, New Orleans; Joseph H. Pratt, Boston; G. C. Smith, Boston; J. A. Witherspoon, Nashville, Tenn.; C. Shattinger, St. Louis; R. Alexander Bate, Louisville, Ky.; Arthur C. Bell, Dallas, Tex.; I. I. Lemann, New Orleans; B. W. Fontaigne, Memphis, Tenn.; J. A. Chilton, Van Buren, Mo.; T. J. Ragsdale, Lees Summit, Mo.; D. C. Walt, Little Rock, Ark.; A. H. Vandivort, St. Joseph, Mo.; A. Comingo Griffith, Kansas City, Mo.; Seale Harris, Mobile, Ala.

Dr. W. J. Calvert, Dallas, Tex., read a paper on "A Possible Differential Sign Between Cardiac Dilation and Pericarditis with Effusion." Discussed by Drs. Haven Emerson, New York, and W. J. Calvert, Dallas, Tex.

WEDNESDAY, JUNE 8—MORNING

The Section held a joint meeting with the Section on Pharmacology and Therapeutics for the consideration of papers in a Symposium on the Circulatory Disorders in Acute Infections. For the minutes of this meeting, see minutes of the Section on Pharmacology and Therapeutics.

WEDNESDAY, JUNE 8—AFTERNOON

Dr. Richard C. Cabot, Boston, delivered the Oration on Medicine, entitled, "A Study of Mistaken Diagnoses Based on the Autopsy Findings in One Thousand Cases."

The Chairman announced that the following would serve on the Nominating Committee: Drs. George Dock, New Orleans; Seale Harris, Mobile, Ala., and Horace D. Arnold, Boston.

Dr. William F. Boos, Boston, read a paper on "Magnesium Poisoning: A Study of Ten Cases." Discussed by Drs. P. S. Roy, Washington, D. C.; W. T. Engle, Grand Island, Neb.; Nathan Rosewater, Cleveland; H. E. Dunlop, Canton, Mo.; C. C. Conover, Kansas City, Mo.; J. W. Bolton, Iola, Kan.; L. Leroy, Memphis, Tenn.; J. D. Reid, Pilger, Neb.; W. H. Philp, St. Francis, Ark.; H. R. St. John, Alton, Kan.; G. R. Neff, Farmington, Iowa, and William F. Boos, Boston.

Dr. James B. Herrick, Chicago, read a paper on "Certain Popular but Erroneous Notions Concerning Angina Pectoris." Discussed by Drs. Joseph L. Miller, Chicago; G. W. McCaskey, Fort Wayne, Ind.; Gustav Baar, Portland, Ore.; S. P. Child, Kansas City, Mo.; J. A. Witherspoon, Nashville, Tenn.; Allen A. Jones, Buffalo, N. Y., and James B. Herrick, Chicago.

Drs. Thomas A. Claytor and Walter H. Merrill, Washington, presented a paper on "Orthodiagraphy: Presentation of a Series of Diagrams of the Heart and Aorta, with Explanatory Remarks." Dr. James G. Van Zwaluwenburg, Ann Arbor, Mich., read a paper on "The Diagnostic Value of the Orthodiagram." These two papers were discussed by Drs. Sidney Lange, Cincinnati; Thomas A. Claytor, Washington, and James G. Van Zwaluwenburg, Ann Arbor, Mich.

THURSDAY, JUNE 9—MORNING

The Committee on Nominations nominated the following: Chairman, Dr. A. Allen Jones, Buffalo, N. Y.; Vice-Chairman, Dr. D. C. L. Green, St. Paul, Minn.; Secretary, Dr. Wilder Tileston, New Haven, Conn.; Delegate, Dr. J. A. Capps, Chicago; Alternate, Dr. Alexander Lambert, New York; Orator, Dr. C. F. Hoover, Cleveland.

It was moved, seconded and carried that the Secretary be instructed to cast a ballot for these nominees.

Dr. Kate C. H. Mead, Middletown, Conn., read a paper on "Persistent Patency of the Ductus Arteriosus, Stenosis of the Isthmus of the Aorta, with Degeneration of the Coronaries of the Cardiac Muscle and of the Sino-Auricular Bundle." Discussed by Dr. Wilder Tileston, New Haven, Conn.

Dr. C. F. Hoover, Cleveland, read a paper on "Regional Vasomotor Hypertonus, with a Report of a Case." Discussed by Drs. Judson Daland, Philadelphia, and C. F. Hoover, Cleveland.

Drs. L. F. Barker, A. D. Hirschfelder and G. M. Bond, Baltimore, presented a paper on "The Electrocardiogram in Clinical Diagnosis." Discussed by Drs. M. J. Lichty, Cleveland; John H. Musser, Philadelphia, and A. D. Hirschfelder, Baltimore.

Dr. Claude A. Smith, Atlanta, Ga., read a paper on "Hookworm Infection and its Prevention." Discussed by Drs. Henry B. Ward, Urbana, Ill.; B. B. Bagby, West Point, Va.; C. C. Bass, New Orleans; Morgan Smith, Little Rock, Ark.; William Letterer, Nashville, Tenn.; John William Colbert, Albuquerque, N. M., and Claude A. Smith, Atlanta, Ga.

Drs. Louis B. Wilson and Byrd C. Willis, Rochester, Minn., read a paper on "Pathologic Relationship of Ulcer and Carcinoma of the Alimentary Canal." Discussed by Drs. H. E. Robertson, Minneapolis; J. N. Hall, Denver; Frank Wilbur Foxworthy, Indianapolis; D. C. Walt, Little Rock, Ark.; Charles G. Stockton, Buffalo, N. Y.; Richard Weil, New York; John A. Lichty, Pittsburg, Pa.; Abraham Jacobi, New York; Hugo A. Freund, Detroit; Harvey G. Beck, Baltimore; G. C. Smith, Boston; Frank Smithies, Ann Arbor, Mich.; T. Potter, Indianapolis, and Louis B. Wilson, Rochester, Minn.

Thursday, June 9—Afternoon

Dr. H. D. Arnold, Boston, read a paper on "The Importance of a Low Protein Diet in Chronic Nephritis." Discussed by Drs. G. C. Smith, Boston; P. S. Roy, Washington, D. C., and H. D. Arnold, Boston.

Dr. W. W. Duke, Baltimore, read a paper on "The Relation of Blood Platelets to Bleeding in Certain Cases of Purpura." Discussed by Drs. J. H. Pratt, Boston, and W. W. Duke, Baltimore.

Dr. John D. Dunham, Columbus, Ohio, read a paper on "Clinical Results of Gastroenterostomy for Non-Malignant Diseases." Discussed by Drs. Judson Daland, Philadelphia; M. J. Lichty, Cleveland, Ohio; John A. Witherspoon, Nashville, Tenn.; DeLancy Rochester, Buffalo, N. Y.; A. L. Benedict, Buffalo, N. Y.; Gustav Baar, Portland, Ore., and John D. Dunham, Columbus, Ohio.

Dr. M. J. Lichty, Cleveland, read a paper on "The Influence of Perigastric Lesions on Gastric Secretions, Based on Clinical and Experimental Study." Discussed by Drs. DeLancey Rochester, Buffalo, N. Y.; James T. Pilcher, Rochester, Minn.; A. L. Benedict, Buffalo, N. Y.; G. C. Smith, Boston; Gustav Baar, Portland, Ore.; John A. Lichty, Pittsburg, Pa., and M. J. Lichty, Cleveland, Ohio.

Dr. Gustav Baar, Portland, Ore., read a paper on "Indicanuria." Discussed by Drs. DeLancey Rochester, Buffalo, N. Y.; Judson Daland, Philadelphia; Jay I. Durand, Atlantic City, N. J.; C. Shattinger, St. Louis, and Gustav Baar, Portland, Ore.

Drs. Judson Daland and George E. Pfahler, Philadelphia, presented a paper on "The Roentgen Ray in the Diagnosis of Diseases of the Alimentary Tract." Discussed by Drs. J. N. Hall, Denver; A. W. Crane, Kalamazoo, Mich.; M. J. Lichty, Cleveland, and Judson Daland, Philadelphia.

Friday, June 10—Morning

Dr. Anders Frick, Chicago, read a paper on "The Different Forms of Mediastinal Exudative Pleurisy, with Report of Three Cases." Discussed by Drs. DeLancey Rochester, Buffalo, N. Y.; Frank Smithies, Ann Arbor, Mich., and Anders Frick, Chicago.

Dr. Frank Smithies, Ann Arbor, Mich., read a paper on "The Diagnostic Significance of the Paravertebral Triangle of Percussion Dulness (Grocco's Sign)." No discussion.

Dr. Edward C. Rosenow, Chicago, read a paper on "Autogenous Vaccine Therapy in Endocarditis." No discussion.

Dr. Willard J. Stone, Toledo, Ohio, read a paper on "The Treatment of Typhoid Carriers, with Report of a Case Treated by Inoculations of Typhoid Vaccine." Discussed by Drs. John J. Buettner, Syracuse, N. Y.; James J. Terrill, Galveston, Tex., and Willard J. Stone, Toledo, Ohio.

SECTION ON OBSTETRICS AND DISEASES OF WOMEN

Tuesday, June 7—Afternoon

The Section was called to order at 2 p. m., in Association Hall, Y. M. C. A. Building, by the Chairman, Dr. John G. Clark, Philadelphia.

Dr. William S. Gardner, Baltimore, read a paper on "Infections of the Endometrium." Discussed by Dr. Novak.

Dr. Henry O. Marcy, Boston, read a paper on "The Plastic Surgery of the Pelvic Structures." Discussed by Drs. Gilliam, Gilbert, Hayden, Hall, Shoemaker, Glasgow, Rosenthal, Hinchey and Marcy.

Dr. Sidney A. Chalfont, Pittsburg, read a paper on "Arteriosclerosis of the Uterine Vessels." Discussed by Drs. Novak and Foulkrod.

Dr. Samuel Wyllis Bandler read a paper on "An Ideal Operation for the Cure of Total Prolapse of the Uterus." Discussed by Drs. Carstens, Goffe, awrence, Baldy and Bandler.

Dr. George Erety Shoemaker read a paper on "Papillary Cystadenoma of the Kidney, Associated with Myoma of the Uterus and Spinal Caries." No discussion.

Dr. J. H. Carstens read a paper on "Uselessness of Local Treatment in Puerperal Sepsis." Discussed by Drs. Zinké, Wetherill, Boldt, Glasgow, Schwartz and Carstens.

Wednesday, June 8—Morning

The following papers were read and discussed as a symposium on observations by inventors of operations for retroflexion of the uterus:

Dr. R. C. Coffey, Portland, Ore.: "Plication of the Round and Anterior Fold of the Broad Ligament on the Anterior Surface of the Uterus for Retrodisplacement."

Dr. J. M. Baldy, Philadelphia: "Attachment of Ligaments Posterior to the Uterus."

Dr. D. Tod Gilliam, Columbus, O.: "Intraperitoneal Implantation of Round Ligaments."

Dr. F. F. Simpson, Pittsburg, Pa.: "Intraperitoneal Shortening of Round Ligaments (Simpson operation)."

Dr. A. Goldspohn, Chicago: "Shortening of the Round Ligaments Via the Temporarily Dilated Inguinal Canals Combined with the Bassini Technic in Closure of the Wounds."

Dr. E. C. Dudley, Chicago: "Resumé of the Surgical Treatment of Retrodeviations of the Uterus."

These six papers were discussed by Drs. Montgomery, Murphy, Boldt, Carstens, Barrett, Marcy, Wathen, Massey, Gellhorn, Byford, Baldy, Gilliam and Simpson.

Wednesday, June 8—Afternoon

The meeting was called to order at 2 p. m. by the Vice-Chairman, Dr. C. C. Frederick, Buffalo.

Dr. John G. Clark, Philadelphia, read his Chairman's Address entitled "Embryologic and Anatomic Causes for Obstinate Constipation in Women; Operative Methods for Relief." Dr. E. E. Montgomery of Philadelphia moved that a vote of thanks be given Dr. Clark for his very able presentation. Seconded and carried.

The following five papers were read and discussed as a Symposium on Enteroptosis:

Dr. Richard R. Smith, Grand Rapids, Mich., read a paper on "Enteroptosis, with Special Reference to Its Etiology and Development, and Remarks on the Results of Examination of 400 Women, with Reference to This Condition."

Dr. E. H. Skinner, Kansas City, Mo., read a paper on "The X-Ray in the Diagnosis of Enteroptosis."

Dr. A. W. Crane, Kalamazoo, Mich., read a paper on "Value of the Roentgen Ray in Enteroptosis."

Dr. John H. Musser, Philadelphia, read a paper on "The Physician's Viewpoint."

Dr. A. J. Ochsner, Chicago, read a paper on "The Surgical Viewpoint."

These five papers were discussed by Drs. Einhorn, Coffey, Korsell, Carstens and Crane.

Thursday, June 9—Morning

The Nominating Committee reported the following nominations: Chairman, Dr. Horace G. Wetherill, Denver; Vice-Chairman, Dr. Fred J. Taussig, St. Louis; Secretary, Dr. C. Jeff Miller, Louisiana; Delegate, Dr. A. E. Benjamin, Minnesota; Alternate, Dr. S. W. Bandler, New York.

The report was accepted and the nominees were elected.

The report of the Cancer Committee, Dr. Horace G. Wetherill, Chairman, recommended an active and educational campaign along the lines indicated in the report of the Committee of 1906, and urged anew that the Section on Obstetrics and Diseases of Women cooperate with the Board of Public Instruction on Medical Subjects [now the Council on Health and Public Instruction] in an energetic effort to educate women to an appreciation of the early signs of cancer and to the importance of an examination by a competent physician; and that all available resources be exhausted in an endeavor to impress on each member of the profession his personal responsibility for an early and accurate diagnosis of cancer and a timely removal of the growth by a competent surgeon. On motion of Dr. Dorsett the report was accepted.

Dr. J. Riddle Goffe, New York City, read a paper on "Tuberculosis of the Female Organs of Generation and the Peritoneum." Discussed by Drs. Novak, Frederick, Gilmore, Byford, Gilliam, A. Miles Taylor, and Goffe in closing.

The following four papers were read and discussed as a Symposium on Carcinoma of the Uterus:

Dr. John A. Sampson, Albany, N. Y.: "The Participation of the Glandular System and Tissues Adjacent to the Uterus in Carcinoma of the Uterus."

Dr. J. H. Jacobson, Toledo, O.: "The Results Obtained by the Radical Abdominal Operation for Carcinoma of the Uterus."

Dr. Emil Ries, Chicago: "The Diagnosis of Operability of Carcinoma of the Cervix of the Uterus."

Dr. C. C. Frederick, Buffalo, N. Y.: "Further Observations on the Use of the Cautery in the Treatment of Carcinoma of the Uterus."

These four papers were discussed by Drs. Gellhorn, Peterson, Goldspohn, Mosier, Wetherill, Jacobson and Ries.

THURSDAY, JUNE 9—AFTERNOON

The Vice-Chairman, Dr. C. C. Frederick, Buffalo, N. Y., called the meeting to order at 2 p. m.

Dr. Channing W. Barrett, Chicago, read a paper on "The Place of Hebosteotomy as an Aid to Delivery." Discussed by Drs. Zinke, Foulkrod, Fry, Burns and Barrett.

The report of the Committee on Revision of the Pharmacopeia was presented, and on motion adopted.

The following five papers were read and discussed as a Symposium on Eclampsia:

Drs. E. P. Davis and Collin Foulkrod, Philadelphia: "The Etiology of Eclampsia"; read by Dr. Foulkrod.

Drs. Edwin B. Cragin and Edward T. Hull, New York: "Treatment of Eclampsia, Including a Comparison of the Dangers of Chloroform and Ether in this Condition"; read by Dr. Hull.

Dr. Henry D. Fry, Washington: "Vaginal Cesarean Section in Eclampsia."

Dr. Reuben Peterson, Ann Arbor, Mich.: "Indications for and Technic of Rapid Emptying of the Uterus in the Toxemias of Pregnancy."

Dr. Joseph B. De Lee, Chicago: "The Surgical Treatment of Eclampsia"; read by the Secretary, Dr. C. Jeff Miller.

These five papers were discussed by Drs. Schwartz, Zinke, Carstens, Blondhe, Burns, Rosenthal, Ritter, Foulkrod, Hull, Fry and Peterson.

SECTION ON SURGERY

TUESDAY, JUNE 7—MORNING

The meeting was called to order at 2 p. m. in the Odeon Theater.

Dr. Charles H. Mayo, Rochester, Minn., the Chairman, delivered his address on "Prophylaxis of Cancer."

Dr. A. Primrose, Toronto, Canada, read a paper on "Surgical Treatment of Compression Paraplegia."

Dr. W. W. Grant, Denver, read a paper on "Anastomosis of Facial and Spinal Accessory Nerves and the Distal End of Spinal Accessory, with Descending Hypoglossal."

These two papers were discussed by Drs. J. B. Murphy, J. T. Bottomley, A. Primrose and W. W. Grant.

Dr. Henry H. Sherk, Pasadena, Cal., read a paper on "Injuries of Abdominal Viscera without External Signs of Violence." Discussed by Drs. M. H. Richardson and Hough.

Dr. E. E. Irons, Chicago, read a paper on "Present Status of Vaccinotherapy." Discussed by Drs. J. B. Deaver, A. W. Crane, W. W. Grant and E. E. Irons.

Dr. H. C. Deaver, Philadelphia, read a paper on "Appendicitis in Children, with Report of Five Hundred Cases." Discussed by Drs. L. S. McMurtry, E. Vander Veer, Lucid, M. Rosenthal, H. Tuholske and J. B. Deaver.

WEDNESDAY, JUNE 8—MORNING

Dr. E. H. Ochsner, Chicago, read a paper on "Final Results in Dislocation of the Hip." Discussed by Drs. A. J. Gillette, J. P. Lord and E. H. Ochsner.

Dr. L. W. Ely, New York, read a paper on "Tuberculosis of Adult Knee-Joint, with New Theory and Plan of Operation."

Dr. J. B. Murphy, Chicago, read a paper on "Acute and Chronic Joint Infections and their Surgical Treatment."

These two papers were discussed by Drs. J. T. Moore, Pearse, A. J. Ochsner, J. F. Binnie, L. W. Ely and J. B. Murphy.

Dr. R. Abbe, New York, delivered the Oration on Surgery, entitled "Radium: A Contribution to Surgery."

Dr. A. F. Jonas, Omaha, Neb., read a paper on "Open Treatment of Fractures." Discussed by Drs. E. W. Andrews, Pearse, J. L. Crook and A. F. Jonas.

Dr. J. T. Bottomley, Boston, read a paper on "Congenital Atresia of Ureter." Discussed by Drs. D. N. Eisendrath and S. E. Sanders.

Dr. C. A. L. Reed, Cincinnati, read a paper on "Extracapsular Fixation of Kidney." Discussed by Dr. S. Lloyd.

WEDNESDAY, JUNE 8—AFTERNOON

Dr. T. S. Cullen, Baltimore, read a paper on "Surgical Diseases of the Umbilicus." Discussed by Drs. W. D. Haggard and T. S. Cullen.

Dr. O. C. Gaub, Pittsburg, Pa., read a paper on "Traumatic Rupture of the Fixed Portion of the Male Urethra." Discussed by Drs. H. M. Sherman, Corrigan, P. Syms, Anderson, H. Cabot, H. H. Young and O. C. Gaub.

Dr. D. S. Fairchild, Clinton, Iowa, read a paper on "Surgical Considerations in the Treatment of Chronic Suppurative Nephritis." Discussed by Drs. A. H. Ferguson and D. S. Fairchild.

Dr. Miles F. Porter, Fort Wayne, Ind., read a paper on "Kidney and Ureteral Stone." Discussed by Drs. H. H. Young, Sumter, M. H. Richardson, J. B. Deaver, Elam, M. Ballin, Mahoney, A. D. Bevan and Miles F. Porter.

Dr. T. C. Witherspoon, Butte, Mont., read a paper on "Surgery of Congenital Cystic Kidney." Discussed by Drs. D. N. Eisendrath, C. M. Nicholson, J. E. Moore and T. C. Witherspoon.

Dr. J. F. Percy, Galesburg, Ill., read a paper on "Phrenitis Prostatica." Discussed by Drs. H. N. Moyer and J. F. Percy.

THURSDAY, JUNE 9—MORNING

Dr. R. Winslow, Baltimore, read a paper on "Partial Tyroidectomy in Dementia Præcox." No discussion.

Dr. H. S. Plummer, Rochester, Minn., read a paper on "Diagnosis and Treatment of Esophageal Lesions." Discussed by Drs. W. Meyer and H. S. Plummer.

Dr. George W. Crile, Cleveland, Ohio, read a paper on "Certain Surgical Aspects of Goiter." Discussed by Drs. A. J. Ochsner, A. MacLaren, M. B. Tinker, W. R. Cubbins, C. H. Mayo and George W. Crile.

Dr. A. D. Bevan, Chicago, read a paper on "Surgical Management of Suppurative Peritonitis." Discussed by Drs. W. L. Rodman, W. H. Wathen, J. P. Runyan, Cahill, J. B. Murphy, A. J. Ochsner and A. D. Bevan.

Dr. F. McRae, Atlanta, Ga., read a paper on "Conservative Surgery of Pelvis and Lower Abdomen." Discussed by Drs. A. H. Ferguson, J. M. Baldy, Fowlkes, Schmauss, Murphy and McRae.

The Nominating Committee made the following nominations: Chairman, Dr. George W. Crile; Vice-Chairman, Dr. E. Rixford; Secretary, Dr. J. T. Bottomley; Orator, Dr. George E. Brewer; Delegate, Dr. A. F. Jonas.

The report of the Nominating Committee was accepted and the nominees were elected.

Dr. A. MacLaren, St. Paul, Minn., read a paper on "Some Further Experiences with Drainage of Pelvic Abscess Through the Rectum." Discussed by Drs. J. M. Baldy, M. H. Richardson and A. MacLaren.

THURSDAY, JUNE 9—AFTERNOON

Drs. R. Matas and C. W. Allen, New Orleans, presented a paper on "Temporary and Permanent Occlusion of the Large Arteries with Metallic Bands." Discussed by Drs. George W. Crile, D. N. Eisendrath and C. W. Allen.

Dr. W. L. Rodman, Philadelphia, read a paper on "Diagnosis of Mammary Cancer."

Dr. M. H. Richardson, Boston, read a paper on "Operative Treatment of Cancer of the Breast."

These two papers were discussed by Drs. W. Meyer, P. Syms, H. Tuholske, Miles F. Porter, W. L. Rodman and M. H. Richardson.

Dr. R. C. Coffey, Portland, Ore., read a paper on "Physiologic Implantation of Severed Ureter or Bile Duct into Intestine." Discussed by Drs. A. G. Sullivan, J. W. D. Maury and R. C. Coffey.

Dr. Le Grand Guerry, Columbia, S. C., read a paper on "A Further Consideration of Cholecystenterostomy in Certain Cases of Pancreatitis."

Dr. J. P. Runyan, Little Rock, Ark., read a paper on "Pathology of Gall-Bladder and Gall-Tract."

These two papers were discussed by Dr. Schmauss.

Dr. A. M. Pond, Dubuque, Iowa, read a paper on "Inguinal Hernia Following Appendectomy." Discussed by Dr. E. W. Andrews.

Dr. M. B. Tinker, Ithaca, N. Y., read a paper on "Teaching the Principles of Surgery: The Ideal and the Practical." Discussed by Drs. J. Stewart and L. Hirschman.

Dr. L. J. Hirschman, Detroit, read a paper on "A Simple Operation for Hemorrhoids without Hemorrhage." No discussion.

SECTION ON OPHTHALMOLOGY

TUESDAY, JUNE 7, 1910—MORNING

The Chairman, Dr. W. C. Posey, Philadelphia, called the meeting to order at 2 p. m. in Aschenbroedel Hall, 3535 Pine Street. He then delivered his address on "Examination of the Eyes in the Public Services in the United States."

Dr. W. H. Wilder, Chicago, offered a resolution concerning the Chairman's address, which on motion was adopted, and which recommended that the President of the Association be empowered to appoint a commission to cooperate with the Department of Commerce and Labor and with the Marine Hospital Corps in establishing proper visual standards and tests to govern state and federal pilots. [The text of this resolution is given in THE JOURNAL, June 18, 1910, p. 2069, and its adoption by the House of Delegates is noted on page 2076.]

Dr. R. L. Randolph, Baltimore, read a paper on "Question of Enucleation in Purulent Panophthalmitis, Together with Brief Experimental Study of the Subject." Discussed by Drs. L. Webster Fox, Philadelphia; C. J. Kipp, Newark, N. J.; L. H. Taylor, Wilkesbarre, Pa.; C. H. Williams, Boston; S. L. Ledbetter, Birmingham, Ala.; E. C. Ellett, Memphis, Tenn.; A. E. Prince, Springfield, Ill.; S. L. Ziegler, Philadelphia; Edward Jackson, Denver; Hiram Woods, Baltimore, and R. L. Randolph, Baltimore.

Dr. Percy Fridenburg, New York, read a paper entitled "A Study of Transillumination." Discussed by Dr. Edward Jackson, Denver, and R. D. Gibson, Youngstown, Ohio.

Dr. S. L. Ziegler, Philadelphia, read a paper on "The Radical Treatment of Lacrimonasal Disease by Rapid Dilatation and Allied Measures." Discussed by Drs. H. Moulton, Fort Smith, Ark.; J. L. Thompson, Indianapolis; J. A. Donovan, Butte, Mont.; C. H. Williams, Boston; Mr. J. H. Parsons, London; Drs. John E. Weeks, New York; Hiram Woods, Baltimore, and S. L. Ziegler, Philadelphia.

Dr. Arnold Knapp, New York, read a paper on "Intermittent Closing of the Retinal Arteries." Discussed by Drs. W. C. Posey, Philadelphia; L. Connor, Detroit; William Zentmayer, Philadelphia; J. L. Thompson, Indianapolis; M. Feingold, New Orleans; Wendell Reber, Philadelphia; E. C. Ellett, Memphis, Tenn.; Haughey, Battle Creek, Mich.; A. Greenwood, Boston, and Arnold Knapp, New York.

In the absence of Dr. Alvin Hubbell, Buffalo, a member of the Executive Committee, who was ill, Dr. Lewis H. Taylor, Wilkes-Barre, Pa., was appointed on that committee.

The Committee on Promotion of Family Physician Refracting presented its report, as follows:

REPORT OF COMMITTEE ON PROMOTION OF FAMILY PHYSICIAN REFRACTING

Your committee appointed under resolutions relative to Chairman Hubbell's address, 1909, begs leave to [illegible]

These resolutions affirm that every [illegible] should enable him to do two things; to manag[illegible]ses, and to determine the refractive defects of the eye. These resolutions also instruct your committee to report on methods for insuring such equipment. The problem thus given us is both broad and complicated; broad in that it affects individually every doctor and citizen; complicated in its relations to medical education, state boards of registration, medical societies, medical journals and popular sentiment. With our time limit, the committee has given it such study as was possible and submits the following:

Since economic reasons prevent a great increase of ophthalmologists, we turn to family doctors, who number about 130,000. If these could do simple refracting, and the entire number of eyes were divided among them, each would have about 1,200—a number possible for adequate refractive service. Of these, the most complicated, in population centers, would fall to the ophthalmologist; the simple and those distant [illegible]e family doctor. Thus the profession [illegible], family physicians being the soldiers, [illegible] unitedly able to refract and keep ref[illegible] human eyes.

Family physician refracting will be defined differently by individuals, but your committee defines it as "that training which enables its possessor (1) to recognize a normal ocular fundus with the ophthalmoscope, and (2) by test cards and simple lenses to determine those that give the best sight with least discomfort to simple presbyopes, myopes and hyperopes." The ability to do these two things, with celerity and positiveness, opens the door to such other things as complete his equipment.

To meet the present conditions the medical college curriculum must be adjusted and young physicians and such other physicans as have leisure encouraged to master it. For this the medical society, medical press, medical books and personal friendship must be utilized. Most important is the State Board of Registration. As the people's representative, it should refuse license to those ignorant of simple refraction. Much remains to interest some of these boards in this part of their duty, and especially in their becoming personally qualified therefor. Thus, from start to finish, the work of your committee is educational.

For study of the subject, your Committee held meetings in Atlantic City, New York, Philadelphia, Baltimore and St. Louis. Its members kept in touch with each other by frequent correspondence. Individually its members discussed the matter with fellow doctors, singly or in groups, as opportunity admitted. Rarely did they fail to win to the cause a friend, if time allowed a fair presentation of facts. Not rarely did these friends present novel ideas and helpful suggestions. Thus during a journey with a member of a state board of registration, while discussing the quantity and quality of ophthalmology a family physican ought to be able to practice, the physican said, as a substantial agreement was reached, "Fix up details as briefly as possible, send to me, and I will see that our board requires the same for license." His state now requires simple refracting for license, as he educated his board. Yet he was simply a family physician of good education, faithful in his endeavor to serve the people.

We found objections to family physician refracting mainly based in two classes of reasons—lack of broad comprehension of the subject, or selfish interest. Usually the removal of the first carried the second. All granted that a family physician ought to be qualified for simple refracting, even when conditons forbade its practice, but they doubted its possibility. Often this doubt was removed by showing that family physicians had mastered the art and were practicing it, even under unfavorable conditions. Many ophthalmologists find it hard to realize that simple refraction can be safe, or of practical value. They forget that, while a family doctor may open a felon, amputate a finger, and do other minor surgery easily, he may not operate fo[illegible] time they will learn that the family doctor c[illegible]iple refracting, leaving to the ophthalmologist [illegible], that a knowledge of personal limitations will restrain him from exceeding them; and that his little knowledge will check any tendency to practice in ignorance.

With a view of stimulating state boards of registration to make a practical study of family physican refracting and to adopt such requirements for license as would encourage medical colleges in its teaching, your Committee prepared the following circular letter and mailed a copy, within a sealed envelope, to members of each board:

Nov. 11, 1909.

"Dear Doctor ———————:"

At the late meeting of the Section on Ophthalmology, American Medical Association (eleven hundred members), the undersigned were appointed a committee to promote a working knowledge of simple refraction among family physicians.

It has secured abundant evidence that such knowledge has been acquired and is now used by many physicians, so proving that all medical men can do likewise, if they so desire.

But that the practice may become uniform, it is necessary that the state boards of registration require it for license and medical colleges teach it in course.

Recognizing its importance, the Michigan State Board of Registration, on Feb. 12, 1909, notified medical colleges that thereafter it would grant licenses to practice only to such applicants, as demonstrated, on a living subject, with simple spherical lenses and test types, their working knowledge of simple refraction.

Your Committee is confident that every state board of registration would make a like requirement, if it grasped the situation; and then all medical colleges would qualify their students therefor.

Recalling the fact that our system of medical education makes no adequate provision for training the family physician in simple refraction, and that it is impossible for experts to meet the needs of all the people in this respect, it is plain that this class of cases had no source of relief other than the optician. But if the state boards require a working knowledge of simple refraction for license, the needs of all the people will be fully met by qualified physicians, and the optician resumes his normal vocation as a spectacle merchant.

Recognizing your great influence in medical affairs, and assuming your vital interest in enlarging the field of family practice, your Committee confidently ask your active endeavor to persuade, your state board of registration to require "a working knowledge of simple refraction" from each applicant for license.

Each member of your Committee stands ready to assist you to a fuller understanding of the situation, or to cooperate with you in seeking its relief.

With thanks for your aid, and a report of your success, we remain, dear doctor,

Sincerely yours,
LEARTUS CONNOR, Detroit, Chairman.
A. R. BAKER, Cleveland, Ohio.
J. THORINGTON, Philadelphia.

Further, a copy of this letter was also sent to officers of a few medical societies, medical journals, medical colleges and other leaders in the profession. Courteous replies were promptly received, some seeking further details, that led to extended correspondence. In December, 1909, the State Board of Registration in Nebraska announced that it would require a working knowledge of simple refraction as a condition for license; in January 1910, Vermont and Utah made similar announcement; Michigan had already been operating the same requirement since Feb. 12, 1909. Replies from other states may be summarized thus:

1. In some the laws did not admit of such specific examination and more time was needed to induce legislatures to make needed changes.
2. Other boards reported that as their individual members knew nothing of refraction they were unable to examine applicants thereupon, but that they would keep the matter under consideration and hoped in the near future to qualify themselves.
3. Other boards reported such an unstable political status that they feared any agitation lest they lose what they already possessed; they promised strong efforts for creating a better public sentiment.
4. Some states desired more time for study of methods for making the proposed examinations a success.
5. No state doubted the wisdom of the suggested requirement; and those unable to make it now regretted the inability and hoped to be able to make the requirement in the near future.
6. Much correspondence was required to make clear the best methods for conducting the examinations, the proper text-books, apparatus, etc., under the varying conditions of the boards, which your Committee conducted with its best judgment.

While medical colleges were not appealed to directly, for lack of time, some, on learning of the Michigan State Board of Registration requirements, voluntarily undertook the preparation of their students therefor. The Association of American Medical Colleges invited your Committee to meet it at Baltimore last March and contribute to the untangling of its problems. Two of the members of your Committee were present, the other being prevented by illness from attending. One read a paper on the "Economic Value of Simple Refracting," which was discussed, and both discussed several points relating to simple refraction in the general medical curriculum. Privately they sought to interest members in simple refracting.

MEDICAL JOURNALS

From the editorials relative to simple refraction we can refer only to two brief extracts. The *Boston Medical and Surgical Journal*, Dec. 9, 1909, p. 865, says: "It is apparent that a need exists in the community that has not been met by the medical profession, and we are therefore in complete accord with the efforts of this committee of the Ophthalmic Section of the American Medical Association to impress on medical schools the importance of teaching simple refraction, not in special courses, but rather as part of the general medical discipline. The pressure to bring this about must, no doubt, in a measure come from state boards of registration, but we do not question that the medical schools will be quick to recognize the desirability of instituting such undergraduate instruction. While there will be some opposition by interested parties, we have no doubt that the best interests of the public will ultimately be subserved through the complete assumption of this work by the medical profession, to which it properly belongs."

The *Medical Fortnightly*, St. Louis, Mo., after quoting the Commitee's letter, restates the vexed problem of the itinerant optician and endorses the solution offered, viz., "make doctors good refractionists themselves." It thinks that the medical colleges could easily make space for simple refraction by omitting some of the things now in the course, but absent from every physician's needs in practice. Thus the addition of simple refraction would even lessen the student's burden. "The new movement is a good one and deserves hearty support."

STATE MEDICAL SOCIETIES

The able secretary of the Kentucky State Medical Society last fall secured some reprints of a paper on simple refracting and distributed them among his members. This brought on a lively discussion at its annual meeting, but in the end the practice was endorsed. It is certain that by tactful arrangement the subject could be brought before other state medical societies. Whether the result was approval or disapproval, the facts would receive consideration, and new friends made, which in turn would make other friends, and so the promotion of simple refracting advance. In fact, the movement started in the Michigan State Medical Society in 1908.

SPECIAL CONFERENCE OF OPHTHALMOLOGISTS WITH STATE SOCIETY OFFICERS

On May 3, 1910, the Detroit Ophthalmological Club invited to a Conference on the Economic Value of Family Physician Refracting, the officers of the Michigan State Medical Society; those of the Wayne County Medical Society; those of the Michigan State Board of Registration; the Deans of the Medical Department of the University of Michigan and Detroit Medical College, and two family physicians doing simple refracting. After a discussion lasting several hours, the club unanimously passed the following resolutions, offered by the professor of ophthalmology in Detroit Medical College, Dr. Don M. Campbell:

WHEREAS, Family physician refracting promotes the cooperation of family physician and ophthalmologist; provides physicians adequate to the people's refractive needs; enriches ophthalmology and ophthalmologists; general medicine and family doctor; strengthens medical organisation, and solves the optician problem.

Resolved, That the Detroit Ophthalmological Club endorses the action of the Section of Ophthalmology of the American Medical Association in promoting family physician refracting; the action of the Michigan State Medical Society, in seeking to qualify its members to meet the people's refractive needs; the action of the Kentucky State Medical Society, endorsing the Michigan idea of family physician refracting; the action of medical colleges in substituting family physician ophthalmology for special ophthalmology, and the action of the state boards of registration in Michigan, Vermont, Nebraska and Utah, in requiring for license, a working knowledge of refracting.

Resolved, That the Detroit Ophthalmological Club urge state boards of registration to require (1) for license, family physician refracting, and (2) for the right to practice ophthalmology, a comprehensive laboratory and clinical [illegible] license.

Resolved, That the Detroit [illegible] encourage family physicians to qualify for [illegible] ophthalmologists by equipping themselves for simple refracting.

It is noteworthy that most members of this conference two years previous were antagonistic to the movement. When conditions are favorable your Committee commends the holding of similar conferences. As ophthalmologists become interested they will take the matter up with their county medical *societies*. It is suggested that if they can secure the attendance of one or more family doctors who practice family physician refracting and have them give their actual experience, the outcome will be more.

It will surprise not a few ophthalmologists to learn of the satisfactory, useful refracting done in far away locations.

VIEWS FROM LEADERS IN THE PROFESSION

Space admits quotations from only three. Dr. William C. Gorgas, President of American Medical Association says: "Your circular letter of November 13 is acknowledged. I think the plan you outline is excellent."

Dr. Charles A. L. Reed, Ex-President of the American Medical Association says: "The plan to require a working knowledge of simple refraction by all candidates for medical licensure is capital and distinctively the logical remedy for the "optometric evil" that seems to threaten the eyes of all the people."

Dr. W. W. Grant, of Denver: "Your communication in regard to simple refraction by the family physician is received. It will give me pleasure to advance the action suggested with our state board. I believe the action of your state board of registration to be wise, timely and greatly to its credit."

Your Committee commends wise efforts to secure the attention of leaders in the profession by suitable circular or private letters, especially in keeping them posted as to the places and lines where greatest progress is being made, and suggesting their active effort in some specific direction.

Your Committee recommends:

1. The continued promotion of family physician refracting.
2. The authorization of your Committee to select in each state an auxiliary committee of three physicians, especially adapted to deal with State problems in simple refracting promotion.

LEARTUS CONNOR, Chairman.
ALBERT R. BAKER.
J. THORINGTON.

The Committee for Legislation on Optometry then presented its report, as follows:

REPORT OF COMMITTEE FOR LEGISLATION ON OPTOMETRY

The Committee for Legislation on Optometry report to the Section on Ophthalmology that prior to its appointment at Atlantic City in 1909 *twenty-four states had passed laws* recognizing the optical trade as a quasi-medical profession; that since the Committee took office no states have passed such law. Late in 1909 Massachusetts, Connecticut, Pennsylvania, Illinois, Missouri and Texas rejected "optometry" bills, while in the current year Massachusetts, New Jersey, Maryland and Ohio have followed up the good work by similar action.

The partial medical work of the optician has been tolerated; but, not content with that, he seeks to have his work legalized. In many states the step from toleration to legalization has been easy, as the political activity of the optician has encountered but little resistance from the masterly inactivity of most oculists and general medical practitioners.

Legalization is but a back-door entrance into medical practice, as shown by the curriculum of their schools and the questions asked by their optometry examining boards. If you wish medicine for medical men and ophthalmology for oculists you must at least be active citizens and show actively and aggressively your wishes and your objections in this matter.

We, cognizant of what has happened in the past and what is threatened in the future, say that so-called "optometry" should not be recognized in any way, that we should cry "No recognition and no compromise!" on all occasions.

But in this stand we must ask the active support of our profession in checking this fad, and if such support be accorded we are certain that these advertising tradesmen will make little or no progress in the future.

The American Medical Association will probably publish in the near future a history of the claims, schools and legislative efforts of the opticians, to be used as a text-book or brief by medical societies in the states where this question is still to be fought.

We freely give our efforts, but we ask aid rather than opposition from our own ranks.

Resolutions which will now be read embody our ideas in regard to this entire question.

JOHN C. BOSSIDY.
JAMES THORINGTON.

Dr. H. Woods, Baltimore, offered the following resolution concerning the report of the Committee on Promotion of Family Physician Refracting and moved its adoption:

[illegible] committee appointed by chairman of the [illegible] 1909, on teaching in medical colleges of [illegible] eye and refractive errors:

WHEREAS, The refracting of human eyes is an important part of medical practice; and

WHEREAS, The Section on Ophthalmology of the American Medical Association recommends that "every general practitioner should have the training in ophthalmology which will enable him to manage infectious diseases of the eye and its refractive defects."

Resolved, That the House of Delegates of the American Medical Association (1) requests its Council on Medical Education to arrange a curriculum able to equip medical students with such training, and recommends medical colleges to adopt the same: (2) approves of the state registration boards now requiring it for license; and (3) advises like action by other state registration boards at an early date.

The motion was seconded.

Dr. J. Thorington, Philadelphia, a member of the Committee on Optometry Legislation, offered a resolution concerning the report of the Committee on Optometry Legislation, the text of which is given in THE JOURNAL, June 18, 1910, p. 2069, and which urges that legal recognition of the optometrist as a diagnostician of the diseases of the eye is an infringement on medical practice laws and should not be sanctioned by any state or institution; that referring patients to opticians should be deprecated; that the House of Delegates be requested to publish a history of so-called optometry and optometry colleges and to send copies to officials of state medical societies and to other medical men who are; and that a committee of two members of the Section on Ophthalmology be appointed to furnish the necessary data.

The resolutions of the two committees as given above were passed and sent to the House of Delegates for action. [The approval of that body is noted in The Journal, June 18, p. 2076.]

Wednesday, June 8—Morning

Dr. Mark D. Stevenson, Akron, O., exhibited an instrument for elevating and holding the upper lid in the treatment of ophthalmia neonatorum, or other trouble, to facilitate the application of medicaments to the upper cul-de-sac. Dr. Stevenson also showed a Goodrich No. 7 shut-off, to be used on an irrigator.

Dr. A. Greenwood, Boston, presented an appliance for shutting out surrounding light in examining the interior of the eye with the ophthalmoscope.

Dr. C. H. Williams, Boston, exhibited some correctly colored worsteds for performing the Holmgren color test of the eyes, and explained his method of keeping a record of the examinations of patients for color-blindness.

Dr. G. C. Savage, Nashville, exhibited his muscle indicator and explained how it might be used in the light tests.

Dr. Lucien Howe, Buffalo, Chairman of the Committee on Collective Investigation Concerning the Ocular Muscles, read the report of that committee.

On motion of Dr. J. E. Weeks, New York, the report was accepted and the committee continued. The report was discussed by Dr. Weeks, Dr. Savage and Dr. Howe.

The report of the Committee on Tuberculosis was read by the Chairman, Dr. W. H. Wilder, Chicago. On motion of Dr. Mark D. Stevenson, Akron, O., the report was adopted and the committee ordered continued. The report was discussed by Dr. John Green, St. Louis.

Dr. Edward Jackson, Denver, read a paper on "Tests of Visual Subjective Correction of Ametropia." Discussed by Dr. C. H. Williams, Boston; Dr. F. Park Lewis, Buffalo; Dr. W. H. Leudde, St. Louis, and Dr. E. Jackson, Denver.

On motion of Dr. A. E. Bulson, Jr., Fort Wayne, Ind., the delegate from the Section was directed to present the name of Mr. J. Herbert Parsons, London, the guest of the Section, to the House of Delegates for election as an honorary member of the Association.

Drs. Mark D. Stevenson, Akron, and E. M. Weaver, Akron, O., presented a paper on "Prescribing of Lenses For Close Work." Discussed by Drs. A. G. Bennett, Buffalo; A. E. Bulson, Jr., Fort Wayne, Ind.; A. Greenwood, Boston; S. L. Ledbetter, Birmingham, Ala.; G. C. Savage, Nashville; Joseph S. Lichtenberg, Kansas City, and Mark D. Stevenson, Akron, O.

Dr. F. Park Lewis, Buffalo, N. Y., read a paper on "Prevention of Blindness." Discussed by Drs. A. E. Bulson, Jr., Fort Wayne, Ind.; Lucien Howe, Buffalo, N. Y.; A. Greenwood, Boston; John Green, Jr., St. Louis; J. A. Donovan, Butte, Mont.; G. C. Savage, Nashville, Tenn.; Miss C. C. Van Blarcom, New York; Mr. Elliott, of the Russell Sage Foundation, New York, and Dr. Mark D. Stevenson, Akron, O.

Dr. F. Park Lewis, Buffalo, N. Y., offered the following resolution covering certain recommendations in Dr. Lewis' paper:

Whereas, The American Medical Association has at present a Committee on Ophthalmia Neonatorum, the purpose of which is the prevention of blindness from this disease, and

Whereas, Trachoma, industrial accidents, intermarriage of the blind, and wood alcohol amblyopia are also preventable causes of blindness; therefore, be it

Resolved, That the House of Delegates be requested to appoint a "Committee on the Prevention of Blindness," the membership of which shall consist of the Chairman of the Committee on Ophthalmia Neonatorum and such other members for the investigation of the above causes of blindness as the president may appoint. This Committee shall invite the cooperation of the American Ophthalmological Society and similar organizations.

[The approval of this resolution, with modifications, is noted in The Journal, June 18, page 2076.]

Dr. W. Zentmayer read a paper on "Present Status of the Etiology of Squint." Discussed by Drs. C. D. Wescott, Chicago; G. C. Savage, Nashville; L. Emerson, Orange, N. J., and Dr. W. Zentmayer.

Wednesday, June 8—Afternoon

Mr. J. Herbert Parsons, London, the guest of the Section, delivered his address on "The Effect of Bright Light on the Eyes." No discussion.

Dr. A. E. Davis, New York, read a paper on "Post-Operative Treatment of Strabismus." Discussed by Drs. Nelson M. Black, Milwaukee, Wis.; W. Reber, Philadelphia; G. C. Savage, Nashville, Tenn.; Lucien Howe, Buffalo, N. Y.; W. Zentmayer, Philadelphia, and A. E. Davis, New York.

Dr. V. H. Hulen, Houston, Tex., read a paper on "Advancement Operation in Squint." Discussed by H. H. Briggs, Asheville, N. C.; G. C. Savage, Nashville, Tenn.; F. C. Todd, Minneapolis; Mark D. Stevenson, Akron, O.; John Green, St. Louis, E. C. Ellett, Memphis, Tenn.; V. H. Hulen, Houston, Tex.

Dr. Casey Wood, Chicago, read a paper on "Surgical Treatment of Separation of the Retina." Discussed by Drs. L. Webster Fox, Philadelphia; Oscar Dodd, Chicago; H. Gifford, Omaha, Neb.; S. L. Ziegler, Philadelphia; Hiram Woods, Baltimore; A. Greenwood, Boston, and Casey Wood, Chicago.

Dr. Albert E. Bulson, Jr., Fort Wayne, Ind., read a paper on "The Noguchi Serum Reaction for Syphilis as an Aid to Diagnosis in Eye Lesions." Discussed by Drs. E. V. L. Brown, Chicago, and A. E. Bulson, Jr., Fort Wayne, Ind.

Thursday, June 9—Morning

Dr. H. Hill, Benton Harbor, Mich., exhibited an addition to the trial frame for measuring the near reading focus.

Dr. W. Reber, Philadelphia, presented a circular, concave glass shield on a handle made to fit over the cornea to prevent loss of vitreous in cataract operations. He also presented a pair of magnifying lenses in a spectacle frame with hooks to be attached over the glasses of the operator in doing needling or other operations on the eye. Dr. Allen Greenwood, of Boston, stated that he had devised and had been using the same appliance for twelve years.

Dr. Nelson Black, Milwaukee, presented an appliance to be used on the trial frame when using the red glass to aid in determining diplopia, so that the patient cannot look above, below or to the right or left, but must look through the red glass. It is simply an enlargement of the red glass that fits up against the patient's nose closely.

Dr. C. H. Williams, Boston, presented an apparatus and method for making enlarged prints of microscopic specimens, which gave a sharpness of definition which could not be obtained in the ordinary way.

Dr. H. Gradle, Chicago, showed his modification of the Schietz tonometer.

Dr. H. Gifford, Omaha, Neb., read a paper on "Danger of Sympathetic Ophthalmia From the Use of the Cautery in Treating Iris-Prolapse; with Discussion of Other Methods of Treatment. Discussed by Drs. R. H. T. Mann, Texarkana; J. A. Donovan, Butte, Mont.; Edward Jackson, Denver, and Gifford, Omaha, Neb.

Dr. W. R. Parker, Detroit, read a paper on "Ophthalmia Nodosa, or Caterpillar-Hair Ophthalmia, with Report of a Case." No discussion.

Dr. E. C. Ellett, Memphis, Tenn., read a paper on "Spontaneous Rupture of the Eyeball—A Phenomenon of Glaucoma." Discussed by Drs. J. M. Ray, Louisville, Ky.; S. L. Ledbetter, Birmingham, Ala.; R. H. T. Mann, Texarkana, and E. C. Ellett, Memphis, Tenn.

Dr. Hiram Woods, Baltimore, read a paper on "Auto-intoxication and Allied Intestinal Troubles as a Possible Cause of Certain Vascular and Functional Disturbances." Discussed by Drs. J. F. Shoemaker, St. Louis; Judson Daland, Philadelphia; J. L. Thompson, Indianapolis; L. Connor, Detroit; A. G. Bennett, Buffalo, N. Y.; R. D. Gibson, Youngstown, O.; S. L. Ziegler, Philadelphia, and H. Woods, Baltimore.

Dr. J. E. Weeks, New York, read a paper on "Status of Serum and Vaccine Therapy in Ophthalmology." Discussed by Drs. M. Wiener, St. Louis; H. Gradle, Chicago; H. Gifford, Omaha, Neb.; A. G. Bennett, Buffalo, N. Y.; E. V. L. Brown, Chicago, and J. E. Weeks, New York.

Dr. Wendell Reber, Philadelphia, read a paper on "The Ocular Palsies Associated with the Introduction of Various Solutions into the Spinal Cord for the Induction of Surgical Anesthesia." Discussed by Drs. John Green, Jr., St. Louis; W. W. Graves, St. Louis; Prof. Alfred Saenger, Hamburg, Germany; James Bordley, Baltimore; G. C. Savage, Nashville, Tenn.; and W. Reber, Philadelphia.

Prof. Alfred Saenger, of Hamburg, Germany, the guest of the Section on Nervous and Mental Diseases, was invited to address the Section on Ophthalmology and spoke on the Wilbrandt method of differentiating cortical from basal hemianopsia.

Thursday, June 9—Afternoon

The Executive Committee submitted its report as follows:

Your Committee submit the following recommendations as their report:

First, we recommend that the officers shall so construct the program for next year that the reading and discussion of papers shall continue until noon of Friday, the fourth day, and that clinical demonstrations, if any, shall be given on Friday afternoon.

As to officers of the Section for another year, we recommend A. E. Bulson, Jr., Fort Wayne, for Chairman, as a fitting recognition of his long and faithful services as Secretary, in which office he has grown bald if not gray.

We recommend the "Chesterfield" of Southern Ophthalmology, E. C. Ellett, of Memphis, for Vice-Chairman.

We recommend the vigorous, promising young ophthalmologist, Edgar S. Thompson, of New York City, for Secretary.

Finally, we recommend that John C. Bossidy, of Boston, be made our representative in the House of Delegates.

G. C. SAVAGE,
W. H. WILDER,
LEWIS H. TAYLOR.

Dr. L. Webster Fox, Philadelphia, offered the following resolution, which, on motion, was adopted and ordered transmitted to Governor Crothers of Maryland and Governor Harmon of Ohio:

Resolved, That the thanks of the Section on Ophthalmology of the American Medical Association be extended to Governor Crothers of Maryland, and Governor Harmon of Ohio, for their action in vetoing bills legalizing the practice of so-called optometry.

Dr. A. E. Bulson, Jr., Fort Wayne, Ind., moved that the Chairman appoint a committee of three to represent this Section before the Board of Trustees to discuss the action which prevented the Section on Ophthalmology from having an exhibit and demonstration at the meeting-place of the Section, and to make some satisfactory arrangement with the Board of Trustees for such scientific exhibit and demonstration in the future. Carried. The Chairman appointed on that committee Drs. Albert E. Bulson, Jr., Fort Wayne, Ind.; Casey Wood, Chicago, and Edward Jackson, Denver.

Dr. A. E. Bulson, Jr., Fort Wayne, Ind., brought up the question of the establishment by the Section of a fund to be known as the Herman Knapp Testimonal Fund, said fund to be used for the following purposes, or for such purposes as might be agreed on by the Section or the committee provided for the purpose of taking charge of the fund:

1. A Knapp Medal to uninvited contributors for original work in ophthalmology or a summary of the literature, or some contribution of such a highly meritorious character in the field of ophthalmology as would warrant the granting of a medal.
2. A prize or medal to be given to those who are invited to contribute on some special topic or work.
3. A portion of the fund to be used to meet the expenses of the scientific exhibit and various practical demonstrations.
4. A portion of the fund to make provision for incidental expenses of the Section.
5. A portion to make provision for the expenses of committees carrying on scientific work, as, for instance, the Committee on Tuberculous Diseases of the Eye, etc.
6. A portion to make provision for the contingent expenses of the Section not met by the Association, as expenses for postage, etc., now paid by the Secretary.
7. A portion to make provision for the local expenses of invited guests or guests of honor of the Section.
8. A committee of five to be appointed to carry out the above purposes of securing a fund in accordance with a circular already sent to the members, on which the sum of about $400 had been collected, and to have charge of and administer the fund, one member of said committee to be appointed for one year, another for two years and another for three years, thus changing the membership of the board each year.

Dr. G. C. Savage, Nashville, Tenn., made a motion, which was seconded and carried, that the Section on Ophthalmology approve of the plans and purposes of the Herman Knapp Testimonial Fund as outlined by Dr. Bulson.

Dr. John E. Weeks, New York, moved that the committee consist of the Chairman and Secretary of this Section and the Executive Committee of the Section. *Seconded and carried.*

REPORT OF THE COMMITTEE ON THE SMITH OPERATION FOR CATARACT

The Committee on the Smith Operation for Cataract submitted a report as follows:

The committee appointed by this Section at Atlantic City last year, to report on the merits of the Smith operation as applied to American patients, begs leave to report progress and asks for more time. The *time since its* circular was issued has been too short to gather enough cases to do justice to the operation. If this committee is continued it will insist that all operations reported to it shall be mad [illegible] neral plan laid down by Colonel Smith, and [illegible] s recorded in the *Ophthalmic Record*, Februa [illegible] a record of 25,000 operations has given him the right to say just how a Smith operation shall be performed.

D. W. GREEN,
ARNOLD KNAPP,
EDWARD JACKSON,
CASEY WOOD,
WALTER R. PARKER, Secretary.

On motion of Dr. L. Webster Fox the report was received and the committee continued.

Dr. G. C. Savage, Nashville, Tenn., read a paper on "Cataract-in-Capsule Extraction by a New Means and a New Method."

Dr. J. L. Thompson, Indianapolis, read a paper on "My Experience in the Operation for Cataract."

These two papers were discussed by Drs. T. H. Wood, Nashville, Tenn.; A. E. Bulson, Jr., Fort Wayne, Ind.; D. W. Green, Dayton, Ohio; L. Webster Fox, Philadelphia; J. L. Thompson, Indianapolis, and G. C. Savage, Nashville, Tenn.

Dr. Allen Greenwood, Boston, read a paper on "Filtering Cicatrix for Chronic Glaucoma, with Report of Cases Operated on by the Method of LaGrange." Discussed by Drs. J. E. Weeks, New York; H. Gifford, Omaha, Neb., and A. Greenwood, Boston.

Dr. G. C. Savage, Nashville, explained that Dr. F. P. Calhoun, Atlanta, on account of the illness of his father, a member of the Association, could not be present to read his paper on "Plastic Surgery of the Eyelids, Using the Wolfe Graft," and moved that the paper be postponed and put on the program for next year. Carried.

Dr. S. L. Ziegler, Philadelphia, moved that a message of condolence be sent from the Section to Dr. Calhoun on the illness of his father. The Secretary was so instructed.

SECTION ON LARYNGOLOGY AND OTOLOGY

TUESDAY, JUNE 7—AFTERNOON

The Chairman, Dr. Chevalier Jackson, Pittsburg, called the meeting to order at 2:30 p. m., in Sodality Hall..

Dr. Jackson delivered the Chairman's Address, entitled, "Esophageal Stricture Following the Swallowing of Caustic Alkalies."

Dr. E. Fletcher Ingals, Chicago, made a motion, which was passed, that the subject be referred to the Committee on Pharmacy with the request that they do what may be necessary to secure the proper labeling of these dangerous substances.

Dr. Holger Mygind, Copenhagen, Denmark, the foreign guest of the Section, delivered an address, "In Memoriam: Wilhelm Meyer."

Dr. Dunbar Roy, Atlanta, Ga., read a paper entitled "Clinical Observations on Nasal Diphtheria." Discussed by Drs. W. E. Casselberry, Chicago; B. R. Shurly, Detroit; Max Goldstein, St. Louis; J. A. Stucky, Lexington, Ky.; Henry Horn, San Francisco; G. L. Cott, Buffalo; Fletcher Ingals, Chicago; Otto Glogau, New York; C. M. Miller, Richmond; and Dr. Dunbar Roy, Atlanta, Ga.

Dr. Ross Hall Skillern, Philadelphia, read a paper on "The Comparative Pathology of Hyperplastic and Suppurative Ethmoiditis," with lantern-slide demonstration. Discussed by Drs. W. L. Ballinger, Chicago; W. E. Casselberry, Chicago; G. P. Marquis, Chicago; O. T. Freer, Chicago; W. L. Ballinger, Chicago; and R. H. Skillern, Philadelphia.

WEDNESDAY, JUNE 8—MORNING

Dr. Henry Horn, San Francisco, read a paper on "The Bronchoscopic Treatment of Bronchial Asthma." Discussed by Drs. E. Fletcher Ingals, Chicago; Chevalier Jackson, Pittsburg; W. E. Casselberry, Chicago; W. S. Anderson, Detroit; and Henry Horn, San Francisco.

Dr. Justus Matthews, Rochester, Minn., read a paper on "Observations on the Vocal Cords in One Thousand Cases of Goiter." Discussed by Drs. W. E. Casselberry, Chicago; G. F. Cott, Buffalo; Henry Horn, San Francisco; G. P. Marquis, Chicago; and Justus Matthews, Rochester, Minn.

The following three papers were read and discussed as a Symposium on Faucial Tonsils:

Dr. Robert Levy, Denver, "The Tuberculous Tonsil."

Dr. Joseph C. Beck, Chicago, "Conditions Demanding Enucleation of Faucial Tonsils."

Dr. Burt R. Shurly, Detroit, "The Difficulties Associated with the Operation for Enucleation of the Faucial Tonsils, and Contraindications for This Procedure."

These three papers were discussed by Drs. A. H. Andrews, Chicago; W. E. Sauer, St. Louis; W. F. Welty, San Francisco; J. E. Logan, Kansas City; O. T. Freer, Chicago; F. E. Auten, Belleville, Ill.; Max Goldstein, St. Louis; B. D. Sheedy, New York; Henry Horn, San Francisco; and J. C. Beck, Chicago.

WEDNESDAY, JUNE 8—AFTERNOON

Dr. Burt R. Shurly offered a resolution that a committee be appointed by the chair to draw up resolutions in memoriam of Drs. Stubbs and King, which was adopted, and the chair appointed Drs. Shurly, Pierce and Goldstein as such committee.

The following three papers were read and discussed as a Symposium on Otitic Meningitis:

Dr. E. B. Dench, New York, "Symptomatology and Diagnosis of Meningitis of Otitic Origin."

Dr. S. MacCuen Smith, Philadelphia, "Indications for Surgical Interference for the Relief of Otitic Meningitis."

Prof. Holger Mygind, Copenhagen, Denmark, "The Surgical Treatment of Otitic Meningitis."

These three papers were discussed by Drs. Norval H. Pierce, Chicago; J. A. Stucky, Lexington, Ky.; W. F. Welty, San Francisco; C. M. Brown, Buffalo; Scholtz, St. Louis; Otto Glogau, New York; E. P. Dench, New York; S. M. Smith, Philadelphia; and Holger Mygind, Copenhagen, Denmark.

On motion of Dr. MacCuen Smith, the delegate from the Section was instructed to recommend to the House of Delegates that Prof. Holger Mygind, Copenhagen, Denmark, be made an honorary member of the Association.

Dr. F. P. Emerson, Boston, read a paper on "The Results of the Operation of Submucous Resection of the Septum in Private Practice."

Dr. Clyde E. Purcell, Paducah, Ky., read a paper on "Submucous Resection of the Nasal Septum."

These two papers were discussed by Drs. J. O. Roe, Rochester, N. Y.; O. T. Freer, Chicago; Scholtz, St. Louis; B. D. Sheedy, New York; W. L. Ballinger, Chicago; O. Tydings, Chicago; G. Sluder, St. Louis; James Steffens, Chicago; L. P. Emerson, Boston; and C. E. Purcell, Paducah, Ky.

Thursday, June 9—Morning

The Vice-Chairman, Dr. George F. Cott, Buffalo, presiding, the election of officers took place.

The report of the Executive Committee, Dr. S. MacCuen Smith, Philadelphia, Chairman, recommended the following as officers for the ensuing year: Chairman, Dr. Dunbar Roy, Atlanta, Ga.; Vice-Chairman, Dr. W. E. Sauer, St. Louis; Secretary, Dr. George E. Shambaugh, Chicago; Delegate, H. W. Loeb, St. Louis.

On motion, duly seconded, the report of the Executive Committee was accepted and the Chairman instructed to cast the ballot for the nominees.

Dr. S. MacCuen Smith, on behalf of the Executive Committee, made a motion, which was seconded and adopted, that in the future the senior member of that Committee be recommended to the Section for the next member of the House of Delegates.

An Exhibition of Patients, Instruments and Specimens was then held.

Dr. Greenfield Sluder, St. Louis, demonstrated a method of removing tonsils, in their capsule, with a modified MacKenzie tonsillotome, and exhibited a number of tonsils so removed, and patients who had been operated on by this method, showing the after-results.

Dr. C. A. Leavy, St. Louis, exhibited a case of laryngeal stenosis.

Dr. Max Goldstein, St. Louis, showed a case of angioma cavernosa of the uvula, and described the method of its removal. He also showed an interesting case of paralysis of the vocal cords.

Dr. W. E. Sauer, St. Louis, exhibited a case of osteoma of the nasal process of the maxillary bone; and, a case of thrombosis of the lateral sinus, which had occurred without involvement of the middle ear.

Dr. Mark D. Stevenson, Akron, Ohio, exhibited a new ear-drain made of cotton covered with gauze, of round form, which could be cut into convenient lengths, and used by the patient, who could change it at frequent intervals.

Dr. H. W. Loeb, St. Louis, showed a case in which laryngectomy had been done six years previously for epithelioma of the larynx; the patient, a working man, bricklayer, had been able to continue his work ever since very satisfactorily. At home he could express himself so as to be understood by his family.

Dr. Max Goldstein, St. Louis, showed a patient, a young girl of 17, who had been totally deaf for five years and who in two months of systematic teaching had acquired a knowledge of lip reading by which she could communicate with others. Discussed by Prof. Holger Mygind, Copenhagen, Denmark.

Dr. Otto Glogau, New York, exhibited a submucous septum saw, for removing the deviated bony portion of the deflected septum.

Dr. Henry Horn, San Francisco, exhibited an instrument or apparatus for determining the presence of pus in the accessory cavities by means of negative pressure.

Dr. J. D. Heitger, Kalamazoo, Mich., exhibited a device for warming the laryngeal mirror by means of an attachment to the ordinary electric socket.

J. W. Radu, Tonawanda, N. Y., showed an improvement on the diagnostic lamps to be used with battery or street currents, which produced a perfectly white light instead of a yellow one, and gave no heat. This closed the exhibition.

Dr. Sydney Lange, Cincinnati, read a paper on "The Pathology of Mastoiditis as Revealed by the X-ray. Discussed by Drs. Henry Horn, San Francisco; C. F. Welty, San Francisco; Frank E. Auten, Belleville, Ill.; and S. Lange, Cincinnati.

Dr. Frank C. Todd, Minneapolis, read a paper on "Neuralgias and Functional Disturbances Occurring in the Head and Neck Arising from Infections in and About the Tonsils." Discussed by Drs. Lafayette Page, Indianapolis; Frank E. Auten, Belleville, Ill.; MacLaren, Oklahoma; C. F. Welty, San Francisco; H. B. Lemere, Omaha, Neb.; George F. Cott, Buffalo; and Frank C. Todd, Minneapolis.

Dr. George W. Boot, Evanston, Ill., read a paper on "The Development of the Human Temporal Bone." Discussed by Dr. George E. Shambaugh, Chicago.

Dr. Will Walter, Chicago, read a paper on "A Study of the Bacterial Flora of the Nasal Mucosa." Discussed by Drs. E. R. Lewis, Dubuque, Iowa; W. S. Anderson, Detroit; and W. Walter, Chicago.

Dr. Henry Horn, San Francisco, demonstrated preparations showing (a) "Cholesteatoma of Middle Ear with Defect in the Horizontal Semicircular Canal and Infection of the Labyrinth"; (b) "Cholesteatoma of Middle Ear with Defect in Horizontal Canal Without Infection of the Labyrinth." Discussed by Dr. George E. Shambaugh, Chicago.

Thursday, June 9—Afternoon

The Vice-Chairman, Dr. George Scott, Buffalo, N. Y., presided.

The committee appointed to draw up resolutions in memoriam of Drs. Stubbs and King asked for further time in which to gather biographic data, and asked to be empowered to submit one copy of report to the Secretary to be spread on the minutes, and a copy to be sent to the respective families. On motion of Dr. J. J. Kyle, the request of the committee was granted.

The following papers were read and discussed as a Symposium on Labyrinthine Suppuration:

The paper of Dr. Jaques Holinger, Chicago, on "The Pathology and Prognosis of Internal Ear Complications Resulting from Inflammatory Middle Ear Diseases," was read by Dr. B. R. Shurly, Detroit, Dr. Holinger being absent because of illness.

Dr. L. K. Guggenheim, St. Louis, gave a lantern-slide demonstration of specimens, showing the pathology of internal ear disease.

Dr. J. R. Fletcher, Chicago, read a paper on "The Symptoms and Diagnosis of Infections of the Labyrinth Resulting from Chronic Suppurative Otitis Media."

Dr. George E. Davis, New York, read a paper on "The Present Status of Vertigo Considered from a Diagnostic Standpoint."

The three papers, with the lantern-slide demonstration, were discussed by Drs. A. B. Duel, New York; Prof. Holger Mygind, Copenhagen, Denmark; George F. Cott, Buffalo; C. F. Welty, San Francisco; George E. Shambaugh, Chicago; Robert Barclay, St. Louis; C. M. Brown, Buffalo; L. K. Guggenheim, St. Louis; Henry Horn, San Francisco; Otto Glogau, New York; J. R. Fletcher, Chicago; and G. E. Davis, New York.

SECTION ON NERVOUS AND MENTAL DISEASES

Tuesday, June 7—Morning

The meeting was called to order at 2 p. m., in the St. Louis University Library, by the Chairman, Dr. Theodore Diller, Pittsburg, who then read his address.

A committee, consisting of Dr. Collins and Dr. Langdon, was appointed to prepare resolutions regarding the death of Dr. Wharton Sinkler.

Dr. Alfred Saenger, of Hamburg, Germany, was, on motion, recommended for honorary membership. [The House of Delegates approved.]

A resolution deprecating the custom of printing details of suicides in the secular press on account of the harmful, suggestive effect on certain individuals, and requesting the Legislative Committee to be instructed to secure, if possible, the enactment of a national law forbidding the use of the mails to newspapers publishing such details, and making it a misdemeanor to publish them, was referred to the Executive Committee.

Dr. Joseph Collins, New York, read a paper on "The Urgent Need of Hospitals for the Study and Treatment of Nervous Diseases."

Dr. L. Vernon Briggs, Boston, read a paper on "Prevention of Insanity by the Treatment of Incipient Cases in General Hospitals."

Dr. Irwin H. Neff, Foxboro, Mass., read a paper on "The State Care of the Inebriate."

These three papers were discussed by Drs. Alfred Saenger, Hamburg, Germany; Charles L. Dana, New York; T. D. Crothers, Hartford, Conn.; F. P. Norbury, Kankakee, Ill.; A. E. Sterne, Indianapolis; Frank R. Fry, St. Louis; Philip Zenner, Cincinnati; Hugh T. Patrick, Chicago; Theodore Diller, Pittsburg; Haldor Sneve, St. Paul, Minn.; Herman H. Hoppe, Cincinnati; Joseph Collins, New York; L. Vernon Briggs, New York; and Irwin H. Neff, Foxboro, Mass.

The Chairman appointed as an Executive Committee, and also as a Committee on Nomination of Officers: Drs. Charles L. Dana, New York; H. T. Patrick, Chicago; and F. W. Langdon, Cincinnati.

Dr. Herbert J. Hall, Marblehead, Mass., read a paper on "Manual Work in the Treatment of the Functional Nervous Diseases."

Dr. Haldor Sneve, St. Paul, Minn., read a paper on "The Treatment of Nervous Diseases by Gymnastic and Massage."

These two papers were discussed by Drs. C. R. Woodson, St. Joseph, Mo.; John Punton, Kansas City, Mo.; Frank R. Fry, St. Louis; Philip Zenner, Cincinnati; C. P. Emerson, Clifton Springs, N. Y.; L. H. Mettler, Chicago; Theodore Diller, Pittsburg, Pa.; Herbert J. Hall, Marblehead, Mass.; and Haldor Sneve, St. Paul, Minn.

Wednesday, June 8—Morning

Dr. H. E. Robertson, Minneapolis, read a paper on "Pathology of Anterior Poliomyelitis."

Dr. David Silver, Pittsburg, Pa., read a paper on "The Surgical Treatment of Anterior Poliomyelitis."

These two papers were discussed by Drs. Archibald Church, Chicago; L. H. Mettler, Chicago; P. Bassoe, Chicago; A. L. Skoog, Kansas City; Arthur S. Hamilton, Minneapolis; Nathaniel Allison, St. Louis; Frank R. Fry, St. Louis; C. R. Woodson, St. Joseph, Mo.; C. H. Hughes, St. Louis; H. E. Robertson, Minneapolis; and David Silver, Pittsburg.

Wednesday, June 8—Afternoon

Dr. Herman H. Hoppe, Cincinnati, read a paper on "The Topographical Diagnosis of Subtentorial Tumors."

Dr. Frank Warren Langdon and Simon P. Kramer, Cincinnati, presented a paper on "Brain Tumor of the Psychomotor Area."

Dr. Julius Grinker, Chicago, read a paper on "Tumor of the Cerebello-Pontile Angle."

These three papers were discussed by Drs. C. H. Hughes, St. Louis; George W. Hall, Chicago; A. E. Sterne, Indianapolis; Charles L. Dana, New York; Theodore Diller, Pittsburg, Pa.; D'Orsay Hecht, Chicago; H. H. Hoppe, Cincinnati; and Julius Grinker, Chicago.

Drs. Edward E. Mayer and Otto C. Gaub, Pittsburg, Pa., presented a paper on "Intradural Tumor of Lower Cervical Cord with Operation."

Discussed by Drs. Theodore Diller, Pittsburg, Pa.; Julius Grinker, Chicago; Charles L. Dana, New York; and Edward E. Mayer, Pittsburg, Pa.

Dr. Archibald Church, Chicago, read a paper on "Nervous and Mental Disturbance at the Male Climacteric." No discussion.

Dr. Charles L. Dana, New York, read a paper on "Study and Interpretation of Pains and Dysthesias." Discussed by Drs. Frank R. Fry, St. Louis; John Punton, Kansas City, Mo.; Sanger Brown, Chicago; L. H. Mettler, Chicago; Julius Grinker, Chicago; C. A. Wingerter, Wheeling, W. Va.; William W. Graves, St. Louis; Theodore Diller, Pittsburg; Charles L. Dana, New York.

A resolution was adopted by rising vote in memory of the late Wharton Sinkler.

Dr. E. M. Hummel, New Orleans, read a paper on "Syphilitic Disease of Arteries of the Central Nervous System, with Detailed Report of a Case." Discussed by Drs. William W. Graves, St. Louis; George A. Moleen, Denver; Sanger Brown, Chicago; Theodore Diller, Pittsburg, and E. M. Hummel, New York.

Dr. A. L. Skoog, Kansas City, Mo., read a paper on "Amyotonia Congenita." Discussed by Dr. Theodore Diller, Pittsburg, Pa.

Dr. E. Bosworth McCready, Pittsburg, Pa., read a paper on "The Relation of Stuttering to Amusia." No discussion.

Thursday, June 9—Morning

The following officers of the Section for 1911 were elected: Chairman, W. A. Jones, Minneapolis; Vice-Chairman, Herman H. Hoppe, Cincinnati; Secretary, E. E. Southard, Boston; Delegate, Theodore Diller, Pittsburg, Pa.; Alternate, J. H. McBride, Pasadena, Cal.

The resolution deprecating the custom of printing details of suicides was adopted as the sense of the Section, and this action was ordered referred to the House of Delegates of the American Medical Association for action. [See next page, first column; see also The Journal, June 18, 1910, page 2076.]

Dr. Alfred Saenger, Hamburg, Germany, read an address on "Choked Disc in Its Relation to Cerebral Tumor and Trepanning." Discussed by Drs. J. Herbert Parsons, London; Julius Grinker, Chicago; J. Bordley, Jr., Baltimore; N. M. Black, Milwaukee, Wis., and Alfred Saenger, Hamburg, Germany.

Dr. Alfred Saenger, Hamburg, Germany, illustrated and discussed Wilbrand's prism test.

Dr. W. W. Graves presented two cases, one of brain tumor and another of a condition of hemianopsia, etc., resulting from skull fracture. Discussed by Dr. Alfred Saenger, Hamburg, Germany.

Dr. John Punton, Kansas City, Mo., read a paper on "The Plea of Insanity as a Defense for Crime and Its Remedy." Discussed by Drs. Louise G. Robinovitch, New York; David S. Booth, St. Louis; A. E. Sterne, Indianapolis; George A. Moleen, Denver; C. W. Thierny, St. Louis; L. V. Briggs, Boston; C. A. Wingerter, Wheeling, W. Va.; C. R. Woodson, St. Joseph, Mo.; Edward Bow, Jacksonville, Ill.; John Punton, Kansas City, Mo.; S. G. Burnett, Kansas City, Mo., and Sanger Brown, Chicago.

Drs. W. A. Jones and Arthur S. Hamilton, Minneapolis, presented a paper on "Hemiplegia Following Acute Infections." Discussed by Drs. M. M. Perry, Parsons, Kan.; Sanger Brown, Chicago; L. H. Mettler, Chicago, and W. A. Jones, Minneapolis.

Dr. George E. Pettey, Memphis, Tenn., read a paper on "The Treatment of Acute Ailments Occurring in Persons Addicted to Narcotic Drugs." No discussion.

Dr. George Edward Fell, Buffalo, N. Y., read a paper on "Twenty Years of Electrocution." No discussion.

SECTION ON PREVENTIVE MEDICINE AND PUBLIC HEALTH

Tuesday, June 7—Afternoon

The Section was called to order at 2 p. m., in Association Hall, by the Chairman, Dr. J. N. Hurty, Indianapolis.

The Chairman read his address on "The Bookkeeping of Humanity." On motion of Dr. P. M. Townsend, Marshalltown, Iowa, duly seconded, the paper was referred to a committee of three, appointed by the Secretary, Dr. Marshall L. Price, Baltimore (temporarily acting as chairman), as follows: Dr. W. R. Batt, Harrisburg, Pa.; Dr. C. H. Jones, Baltimore, and Dr. P. M. Townsend, Marshalltown, Iowa. Discussed by Drs. Prince A. Morrow, New York; W. F. Snow, Sacramento, Cal.; Arthur Reynolds, Chicago; P. M. Townsend, Marshalltown, Iowa; Henry B. Hemenway, Evanston, Ill., and J. N. Hurty, Indianapolis.

Dr. Walter P. Bierring, Iowa City, Iowa, read a paper on "The Rôle of Pathology and Physiology in Preventive Medicine."

Dr. Joseph P. Remington, Philadelphia, read a paper on "The Rôle of Pharmacy in Preventive Medicine."

These two papers were discussed by Drs. Seneca Egbert, Philadelphia, and William Le Roy Dunn, Asheville, N. C.; W. A. Evans, Chicago; Liston H. Montgomery, Chicago; J. N. Hurty, Indianapolis; George Edward Fell, Buffalo, N. Y.; Walter P. Bierring, Iowa City, Iowa, and Joseph P. Remington, Philadelphia.

Dr. G. Lloyd Magruder, Washington, D. C., read a paper entitled "Further Observations on the Milk-Supply of Washington, D. C.," with illustrative lantern slides. Discussed by Drs. William C. M. Woodward, Washington, D. C.; William H. Welch, Baltimore; B. Franklin Royer, Harrisburg, Pa.; William Edward Grant, Louisville, Ky.; Seneca Egbert, Philadelphia. A vote of thanks to the author of the paper, Dr. Magruder, was moved by Dr. W. Forrest Dutton, Carnegie, Pa., and given.

The Secretary, on behalf of the officers of the Section, then nominated for associate membership in the American Medical Association John M. Glenn of New York, director of the Russell Sage Foundation. The report was adopted, and the nomination referred to the House of Delegates.

Wednesday, June 8—Morning

Dr. Henry B. Hemenway, Evanston, Ill., offered the following resolution:

> According to the published reports of the Census Bureau there has been a great and marked increase in the number of suicides in this country. The death-rate from this cause per hundred thousand was as follows: 1902, 12.7; 1903, 13.9; 1904, 14.8; 1905, 16.1; 1906, 14.3; 1907, 16.2; 1908, 18.5. An increase of practically 50 per cent. in the seven years demands investigation and energetic action. The publication in the secular papers of these unfortunate occurrences can do no one good; on the other hand, it is well recognized by those in a position to judge that such publication has a powerful suggestive effect on susceptible individuals, and it is unquestionably one of the most active causes of this form of death; therefore, be it
>
> *Resolved*, That such publication of accounts of suicides is detrimental to the good of the people in this country, and that we request the House of Delegates to take action in the case by requesting the press of the land to stop such publication; and, further, that the Legislative Committee be instructed to further the enactment of a national law forbidding the use of the mails by any paper making such publication; and, further, that the same committee be instructed to assist in the passage of state laws making such publication a misdemeanor and providing suitable punishment therefor.

This resolution was approved by the Section for submission to the House of Delegates. [The House adopted a substitute of similar import. The Journal, June 18, page 2076.]

The Chairman appointed as a Committee on Nominations Drs. W. Forrest Dutton, Carnegie, Pa.; T. R. Crowder, Chicago, and J. E. King, Richmond, Ind.

Dr. Wilmer R. Batt, Harrisburg, Pa., on behalf of the committee to which the Chairman's address was referred, recommended its early publication and wide distribution.

The Chairman explained that he had not, in the session of June 7, 1910, given Dr. G. Lloyd Magruder opportunity to make the final statement in regard to the latter's paper, "Further Observations on the Milk-Supply of Washington, D. C.; Dr. Magruder then spoke.

Dr. Seneca Egbert, Philadelphia, read the Oration on State Medicine and Hygiene. Discussed by Drs. Henry B. Hemenway, Evanston, Ill.; W. A. Evans, Chicago; Rosalie Slaughter Morton, New York; Arthur Reynolds, Chicago; William C. Woodward, Washington, D. C.; John H. White, New Orleans; Mazyck P. Ravenel, Madison, Wis. Dr. Marshall Langton Price, Baltimore, moved a vote of thanks to Dr. Egbert, which was given.

Dr. Henry B. Hemenway, Evanston, Ill., offered the following resolution:

> Whereas: Public health administration is greatly helped by popular education and cannot advance far beyond the state of common knowledge; and
>
> Whereas: Our literary colleges and normal schools to-day give practically no instruction of this kind; and
>
> Whereas: Much of the instruction in the graded schools of the land is based on misinformation; therefore be it
>
> *Resolved*, That such instruction by lectures or otherwise should be given in every such institution of learning, and
>
> *Resolved*, That the House of Delegates be asked to appoint a committee to promote a course of instruction in all literary colleges and normal schools.

This was adopted for submission to the House of Delegates [which referred it to the newly-formed Council on Health and Public Instruction. The Journal, June 18, page 2076.]

Dr. Joseph Collins, New York, read a paper on "The Epidemiology of Poliomyelitis and Cerebrospinal Meningitis." Discussed by J. N. Hurty, Indianapolis.

Dr. Hiram Woods, Baltimore, read a paper on "The Rôle of Ophthalmology in Preventive Medicine. Discussed by Drs. Leartus Connor, Detroit; Prince A. Morrow, New York; Seneca Egbert, Philadelphia; Henry B. Hemenway, Evanston, Ill.; W. Forrest Dutton, Carnegie, Pa.; and Hiram Woods, Baltimore.

Dr. Thomas S. Southworth, New York read a paper on "The Rôle of Pediatrics in Preventive Medicine." No discussion.

Wednesday, June 8—Morning

The following papers were read and discussed as a symposium on Hookworm and Pellagra:

Dr. John D. Long, Washington, D. C.: "Pellagra," illustrated by lantern slides.

Dr. Charles W. Stiles, Washington, D. C.: "Sanitary Phases of the Hookworm Problem," illustrated by lantern slides.

Dr. Allen W. Freeman, Richmond, Va.: "Hookworm Disease: The Farm; the Next Point of Attack in Sanitary Progress."

These three papers were discussed by Drs. Marshall Langton Price, Baltimore; John L. Jelks, Memphis, Tenn.; C. C. Bass, New Orleans; James W. Babcock, Columbia, S. C.; William L. Medling, Nashville, Tenn.; Seneca Egbert, Philadelphia; John D. Long, Washington, D. C.; Charles W. Stiles, Washington, D. C.; J. N. Hurty, Indianapolis, Ind., and Allen W. Freeman, Richmond, Va.

Dr. W. Forrest Dutton, Carnegie, Pa., read a paper on "Present-Day Problems and Progress in Prevention of Typhoid Fever,"

Dr. George Edward Fell, Buffalo, N. Y., read a paper on "The Currents at the Eastern End of Lake Erie and the Head of Niagara River: Their Influence on the Sanitation of the City of Buffalo, N. Y.," illustrated with lantern slides.

These two papers were discussed by Drs. H. W. Hill, Minneapolis; C. Hampson Jones, Baltimore; Liston H. Montgomery, Chicago; W. Forrest Dutton, Carnegie, Pa., and Seneca Egbert, Philadelphia.

Dr. I. D. Rawlings, Chicago, read a paper on "The Campaign Against Diphtheria and Scarlet Fever in Chicago."

Dr. C. Hampson Jones, Baltimore, read a paper on "What Can Health Departments Do to Control Scarlet Fever?"

These two papers were discussed by Drs. Henry B. Hemenway, Evanston, Ill.; B. Franklin Royer, Harrisburg, Pa.; H. W. Hill, Minneapolis; Seneca Egbert, Philadelphia; R. M. Winn, Hannibal, Mo.; G. Koehler, Chicago; H. Delamater, Kansas City, Mo.; I. D. Rawlings, Chicago, and C. Hampson Jones, Baltimore.

By motion duly made and carried, Papers 15 and 16 were made the first order of business for the ensuing meeting.

Thursday, June 9—Morning

Dr. T. D. Crothers, Hartford, Conn., read a paper on "The Relation of Alcoholism and Drug Addictions to Preventive Medicine." Discussed by Drs. Liston H. Montgomery, Chicago, and J. N. Hurty, Indianapolis.

Dr. W. Forrest Dutton, Carnegie, Pa., Chairman of Committee on Nominations, submitted the following nominations: Chairman, Dr. W. A. Evans, Chicago; Vice-Chairman, Dr. Marshall Langton Price, Baltimore; Secretary, Dr. C. Hampson Jones, Baltimore, Md.; Delegate, Dr. J. N. Hurty, Indianapolis; Alternate, Dr. J. H. White, New Orleans. The Secretary was instructed to cast the ballot for these nominees, and they were declared elected.

Dr. Arthur Reynolds moved the nomination of Dr. W. A. Evans, Chicago, as Orator on State Medicine and Hygiene, which was seconded, and Dr. Evans was elected, and made a stirring speech foreshadowing the creation of a Council on Public Health, whose function should largely be the coordination of work now done nation-wide in the interests of public health.

Dr. W. C. Gorgas, Ancon, Canal Zone, declared his sympathy with the Chairman-Elect's program for widening the scope of the Section.

Dr. Arthur Reynolds, Chicago, moved "That the Chairman of this Section be empowered to appoint such committees as in his judgment seem wise, to carry out the purposes he has outlined." Seconded and carried.

Dr. Miles F. Porter, Fort Wayne, Ind., read a paper on "The Rôle of Surgery in Preventive Medicine." Discussed by Drs. J. N. Hurty, Indianapolis; Seneca Egbert, Philadelphia; Liston H. Montgomery, Chicago; H. W. Hill, Minneapolis, and Walter P. Manton, Detroit.

Dr. Walter P. Manton, Detroit, read a paper on "The Rôle of Obstetrics in Preventive Medicine." Discussed by Drs. J. N. Hurty, Indianapolis; Henry B. Hemenway, Evanston, Ill.; P. M. Townsend, Marshalltown, Iowa; Charles W. Stiles, Washington, D. C.; C. Hampson Jones, Baltimore; Seneca Egbert, Philadelphia, and Walter P. Manton, Detroit.

Dr. J. J. Kyle, Indianapolis, read a paper on "The Rôle of Rhinology and Otology in Preventive Medicine." Discussed by Drs. Robert Levi, Denver; J. D. MacLaren, Norman, Okla.; H. W. Hill, Minneapolis; Liston H. Montgomery, Chicago; William H. Rush, St. Louis, and J. J. Kyle, Indianapolis.

Dr. Hibbert W. Hill, Minneapolis, read a paper on "Acute Epidemic Anterior Poliomyelitis." Discussed by Drs. J. M. Allen, Liberty, Mo.; Hibbert W. Hill, Minneapolis; W. Forrest Dutton, Carnegie, Pa.; Julius Lingenfelder, West Point, Neb., and Seneca Egbert, Philadelphia.

Dr. W. H. Rennie, Washington, D. C., read a paper on "The Relation of Recruiting to Preventive Medicine." Discussed by Drs. Marshall Langton Price, Baltimore, and J. N. Hurty, Indianapolis.

Dr. Henry B. Hemenway, Evanston, Ill., read a paper on "Legal Aspects of Domestic Quarantine." Discussed by Drs. John H. White, New Orleans; B. Franklin Royer, Harrisburg, Pa.; W. A. Evans, Chicago; W. F. Snow, Sacramento, Cal., and Henry B. Hemenway, Evanston, Ill.

The Chairman, with assent of the Section, arranged to send a telegram of sympathy and regret to Dr. H. M. Bracken, Minneapolis, who was reported to be ill with typhoid fever.

Thursday, June 9—Afternoon

Dr. Hyman Cohen, Chicago, read a paper on "House Quarantine." Discussed by Drs. B. Franklin Royer, Harrisburg, Pa.; Seneca Egbert, Philadelphia; I. D. Rawlings, Chicago, and Hyman Cohen, Chicago.

A paper by Dr. John H. White, New Orleans, on "The Permanent Elimination of Yellow Fever from the Earth," was read by Dr. Henry B. Hemenway, Evanston, Ill. No discussion.

Dr. Charles W. Stiles, Washington, D. C., exhibited two models of privies, describing details of construction and choice of color of paint to be applied, stating that flies were attracted by light colors, mosquitoes by dark colors; and further, that he had succeeded in placing privy construction on the manual training curricula of some schools. Discussed by Drs. J. N. Hurty, Indianapolis; Seneca Egbert, Philadelphia, and H. W. Hill, Minneapolis.

Dr. D. T. Quigley, North Platte, Neb., read a paper on "The Work of Prevention in Nebraska." Discussed by Dr. J. N. Hurty, Indianapolis.

Dr. W. A. Evans, Chicago, read a paper on "The Ventilation of School Buildings." Discussed by Drs. Henry B. Hemenway, Evanston, Ill.; Seneca Egbert, Philadelphia; J. N. Hurty, Indianapolis, and W. A. Evans, Chicago.

Dr. Gottfried Koehler, Chicago, read a paper by himself, and Dr. C. S. Clair Drake, Chicago, on "The Prevention of Infant Mortality." No discussion.

Dr. Fred O. Tonney, Chicago, read a paper on "Tuberculosis in the Raw Milk-Supply of Chicago." Discussed by Drs. W. A. Evans, Chicago, and Fred O. Tonney, Chicago.

Dr. B. L. Arms, Boston, read a paper on "The Strauss Reaction for the Diagnosis of Glanders." Discussed by Drs. H. W. Hill, Minneapolis, and B. L. Arms, Boston.

Installation of the officers-elect then followed, and the Section adjourned for 1910.

SECTION ON STOMATOLOGY

Tuesday, June 7—Afternoon

The meeting was called to order by the Chairman, Dr. Thomas L. Gilmer, Chicago, at 2:30 p. m., in Small Hall, Y. M. C. A. Building.

The Chairman then read his address. Discussed by Drs. M. H. Fletcher, Cincinnati; Frederick B. Noyes, Chicago; James E. Power, Providence, R. I.; Eugene S. Talbot, Chicago.

The Chairman appointed the three following as members of the Executive Committee: Drs. William E. Fisher, New York; J. E. Power, Providence, R. I.; Frederick B. Noyes, Chicago.

Dr. Stewart L. McCurdy, Pittsburg, Pa., read a paper on "The Pathology and Treatment of Alveolar Abscess." Discussed by Drs. George V. I. Brown, Milwaukee, Wis.; J. E. Power, Providence, R. I.; William E. Fisher, New York; Eugene S. Talbot, Chicago; Frederick Noyes, Chicago, and C. W. Harned, Iowa City, Iowa.

Dr. Frederick B. Noyes, Chicago, read a paper on "The Relation of the Teeth to the Development of the Jaws and the Face." Discussed by Drs. M. H. Fletcher, Cincinnati; B. E. Lischer, St. Louis; J. Porter Farm, Ardmore, Okla.; Stewart L. McCurdy, Pittsburg, Pa., and Eugene S. Talbot, Chicago.

Dr. Nelson M. Black, Milwaukee, Wis., read a paper on "Improvement in the General Health of Children Having an Inclination toward Nasal Stenosis by Widening the Nasal Arch." Discussed by Drs. J. Porter Farm, Ardmore, Okla.; Richard Summa, St. Louis; Frederick B. Noyes, Chicago; George V. I. Brown, Milwaukee, Wis., and Eugene S. Talbot, Chicago.

Wednesday, June 8—Morning

A Committee on Nominations was appointed as follows: Drs. M. H. Fletcher, Cincinnati; L. P. Bethel, Columbus, Ohio, and J. E. Power, Providence, R. I.

A symposium was presented on "How Shall the Stomatologist be Educated," by Drs. Eugene S. Talbot, Chicago; James E. Power, Providence, R. I.; M. H. Cryer, Philadelphia.

These three papers were discussed by Drs. J. N. Farrar, New York; Arthur R. Dray, Philadelphia; Eugene H. Smith, Boston; M. H. Fletcher, Cincinnati; Stewart L. McCurdy, Pittsburg, Pa.; J. P. Gray, Nashville, Tenn.; N. P. Colwell, Chicago; Arthur Dean Bevan, Chicago; John M. Dodson, Chicago; Frederick B. Noyes, Chicago; G. V. I. Brown, Milwaukee; Fred C. Zapffe, Chicago; H. A. Potts, Chicago; J. M. Matthews, Liberty, Mo.; T. W. Brophy, Chicago.

On recommendation of the Secretary the following resolution was passed:

Resolved, That a committee of three be appointed by the chairman to confer with the Association of American Medical Colleges and the Council on Medical Education of the American Medical Association and with such other bodies and individuals as may be necessary to bring about harmonious results in stomatologic education.

Wednesday, June 8—Afternoon

Dr. M. H. Fletcher, Cincinnati, read a paper entitled "A Study of the Repair of the Cementum." Discussed by Drs. Frederick Noyes, Chicago; G. V. I. Brown, Milwaukee, Wis; T. W. Brophy, Chicago; Eugene S. Talbot, Chicago; William E. Fisher, New York, and Frederick B. Noyes, Chicago.

Dr. Henry R. Harrower, Chicago, read a paper on "Metabolism and Mouth Disease." Discussed by Drs. Eugene S. Talbot, Chicago, and G. V. I. Brown, Milwaukee, Wis.

Dr. Herbert A. Potts, Chicago, read a paper on "The Teeth as a Factor in Pathogenesis."

Dr. Frederick B. Moorehead, Chicago, read a paper on "The Teeth and Alveolar Processes as Points of Entrance for the Tubercle Bacillus."

These two papers were discussed by Drs. James E. Power, Providence, R. I.; M. H. Fletcher, Cincinnati; T. W. Brophy, Chicago; Eugene S. Talbot, Chicago; William E. Fisher, New York; V. P. Blair, St. Louis; Stewart L. McCurdy, Pittsburg, Pa.; H. A. Potts and F. B. Moorehead, Chicago.

The Chairman appointed a Committee on Stomatologic Education, as specified above, as follows: Chairman, Dr. Eugene S. Talbot, Chicago; Dr. H. E. Potts, Chicago, and Dr. Frederick B. Moorehead, Chicago.

Thursday, June 9—Morning

On recommendation of the Nominating Committee, the following officers were elected for the ensuing year: Chairman, Dr. S. L. McCurdy, Pittsburg; Vice-Chairman, Dr. Virgil Loeb, St. Louis; Secretary, Dr. Eugene S. Talbot, Chicago; Delegate, Dr. G. V. I. Brown, Milwaukee, Wis.; Alternate, Dr. M. H. Fletcher, Cincinnati.

Dr. Lee Wallace Dean, Iowa City, Iowa, read a paper on "The Influence on the Nose of Widening the Palatal Arch." Discussed by Drs. G. V. I. Brown, Milwaukee, Wis.; Eugene S. Talbot, Chicago; Stewart L. McCurdy, Pittsburg, Pa.; L. P. Bethel, Columbus, Ohio, and M. H. Fletcher, Cincinnati.

Dr. James E. Power, Providence, R. I., read a paper on "The Value of Vaccines in Oral Surgery." Discussed by Drs. G. V. I. Brown, Milwaukee, Wis.; Stewart L. McCurdy, Pittsburg, Pa.; W. E. Fisher, New York; M. H. Fletcher, Cincinnati; L. W. Dean, Iowa City, Iowa, and Eugene S. Talbot, Chicago.

Dr. G. V. I. Brown, Milwaukee, Wis., read a paper on "The Surgical Principles of Hair-Lip Operation." Discussed by Drs. Stewart L. McCurdy, Pittsburg, Pa., and M. H. Fletcher, Cincinnati.

Dr. Bertha E. Bush, Chicago, read a paper on "The Close Relations between the Physician and the Dentist." Discussed by Dr. Lee Wallace Dean.

Dr. Charles M. Whitney, Boston, read a paper on "The Mouth Lesions of Syphilis and the Dangers Arising Therefrom." Discussed by Dr. Stewart L. McCurdy, Pittsburg, Pa.

Dr. Vida A. Latham, Chicago, read a paper on "Systemic Conditions in Relation to Oral Symptoms; Pain, Fetor and Sepsis." Discussed by Drs. G. V. I. Brown, Milwaukee, Wis., and M. H. Fletcher, Cincinnati.

SECTION ON DISEASES OF CHILDREN

Tuesday, June 7—Afternoon

The meeting was called to order at 2 p. m., in Grand Avenue Presbyterian Church, by the Chairman, Dr. William J. Butler, Chicago, who then read his address entitled, "Enteroptosis in Children."

Drs. Samuel M. Hamill and Kenneth D. Blackfan, Philadelphia, presented a paper on "The Diagnosis and Treatment of Chronic Intestinal Indigestion in Children." Discussed by Drs. H. B. Coit, Newark, N. J.; C. G. Kerley, New York; L. T. Royster, Norfolk, Va.; H. M. McClanahan, Omaha, Neb.; E. E. Graham, Philadelphia; John Lovett Morse, Boston; F. B. Talbot, Boston, and S. M. Hamill.

Dr. Thomas D. Parke, Birmingham, Ala., read a paper on "Further Report of Cases with Complicating Ileocolitis and Probably Due to Acidosis." Discussed by Drs. John Zahorsky, St. Louis; Isaac A. Abt, Chicago, and T. D. Parke, Birmingham, Ala.

Dr. C. Gilmore Kerley, New York, read a paper on "Atypical Scarlet Fever." Discussed by Drs. O. T. Moore, St. Louis; S. E. Munson, Springfield, Ill.; Kepler, Michigan, and C. G. Kerley, New York.

Dr. H. M. Folkes, Biloxi, Miss., read a paper on "Infectious Diseases in Negro Children." Discussed by Drs. L. T. Royster, Norfolk, Va., and H. M. Folkes, Biloxi, Miss.

Dr. John Lovett Morse, Boston, read a paper on "Agar-Agar in the Treatment of Constipation in Childhood." Discussed by Drs. Alfred Friedlander, Cincinnati; C. G. Kerley, New York; Godfrey R. Pisek, New York, and J. L. Morse, Boston.

The Secretary read a letter from Trustees of the American Medical Association concerning the establishment of a pediatric journal, and moved that the Section endorse the proposition and that the matter be referred to the Executive Committee of the Section with power to act. Discussed by Drs. William Butler, Chicago; C. G. Kerley, New York; J. M. Dodson, Chicago; A. C. Cotton, Chicago; D. W. Graham, Chicago; F. S. Churchill, Chicago; G. H. E. Rosamond, Memphis; and J. W. Van Derslice, Chicago.

Wednesday, June 8—Morning

Drs. Jerome S. Leopold, New York, and I. Rosenstern, Berlin, presented a paper on "The Significance of Tuberculides in the Diagnosis of Tuberculosis in Infants." Discussed by Drs. F. C. Neff, Kansas City, Mo.; Frank Gengenbach, Denver; W. D. Hoskins, Indianapolis; C. F. Wahrer, Fort Madison, Iowa; C. G. Kerley, New York, and J. S. Leopold, New York.

Theodore J. Elterich, Pittsburg, Pa., read a paper on "A Clinical Study of a Case of Pseudoleucemic Anemia of Infancy." Discussed by Drs. J. B. Hultgen, Chicago; C. F. Wahrer, Fort Madison, Iowa, and T. J. Elterich, Pittsburg, Pa.

Dr. A. D. Bevan, Chicago, read a paper on "The Surgical Treatment of Congenital Pyloric Stenosis." Discussed by Drs. H. M. McClanahan, Omaha; John Lovett Morse, Boston; Isaac A. Abt, Chicago; E. J. Porteous, Atlantic City, N. J.; C. G. Kerley, New York; H. Stern, New York; Katherine B. Richardson, Kansas City, Mo.; F. B. Talbot, Boston; F. S. Churchill, Chicago; Frank Gengenbach, Denver; H. L. Coit, Newark, N. J.; William Butler, Chicago, and A. D. Bevan, Chicago.

Dr. H. M. McClanahan, Omaha, Neb., read a paper entitled, "A Brief History of the Nebraska Epidemic of Poliomyelitis." Discussed by Drs. C. A. Anderson, Stromsburg, Neb.; E. H. Bartley, New York., and H. M. McClanahan, Omaha, Neb.

Dr. J. W. Van Derslice, Chicago, read a paper on "Rachitis." No discussion.

Dr. Heinrich Stern, New York, read a paper on "Blood-Letting in Children." Discussed by Drs. E. M. Sill, New York; A Jacobi, New York; William Butler, Chicago, and H. Stern, New York.

Dr. H. L. Coit, Newark N. J., presented an instrument for determining temperature in sterilization of milk.

Wednesday, June 8—Afternoon

The following four papers were discussed together:

Dr. A. C. Cotton, Chicago, "Disturbances of Lactation."

Dr. Charles Douglas, Detroit, "Feeding of Fats to Infants and Difficulties Encountered in Feeding Them."

Dr. F. B. Talbot, Boston, "The Digestion of Fat in Infancy."

Dr. Thomas S. Southworth, New York, "Complemental Feeding of the Infant as an Effective Aid in Maintaining Maternal Nursing."

These four papers were discussed by Drs. John Zahorsky, St. Louis; Effa Davis, Chicago; J. P. Sedgwick, Minneapolis; John Lovett Morse, Boston; C. F. Wahrer, Fort Madison, Iowa; Jules M. Brady, St. Louis; C. G. Kerley, New York; A. C. Cotton, Chicago; Charles Douglas, Detroit; F. B. Talbot, Boston, and T. S. Southworth, New York.

Drs. Jerome Alexander and Jesse G. M. Bullowa, New York, presented a paper on "The Influence of Colloidal Protection on Milk." Discussed by Drs. F. S. Churchill, Chicago; E. H. Bartley, New York; Thomas S. Southworth, New York, and Jerome Alexander, New York.

Dr. J. P. Sedgwick, Minneapolis, read a paper on "Creatinin and Creatin Metabolism in Children." No discussion.

Dr. E. H. Bartley, New York, offered the following resolution, which was carried:

> *Resolved*, That the Chairman of this section appoint a committee of three members to be known as the Committee on Hygiene and Publicity to act in conjunction with or under the direction of the proposed Committee on Health and Public Instruction of the American Medical Association.

The Chairman appointed the following on that committee: Drs. E. H. Bartley, New York; A. C. Cotton, Chicago, and Dr. C. G. Kerley, New York.

Thursday, June 9—Morning

Dr. Isaac A. Abt, Chicago, read a paper on "A Case of Amaurotic Family Idiocy with Autopsy and Histologic Report." Discussed by Drs. John Lovett Morse, Boston, and I. A. Abt, Chicago.

Dr. C. C. Rogers, Chicago, read a paper on "Intracranial Surgical Lesions in Children." Discussed by Drs. E. H. Abbott, Elgin, Ill.; C. G. Kerley, New York, and C. C. Rogers, Chicago.

Dr. Samuel Lloyd, New York, read a paper on "Surgical Treatment of Empyema." Discussed by Drs. E. E. Graham, Philadelphia; I. A. Abt, Chicago; C. C. Rogers, Chicago, and Samuel Lloyd, New York.

Dr. J. Ross Snyder, Birmingham, Ala., presented the report of the Nominating Committee, recommending the election of the following officers: Chairman, Dr. Samuel M. Hamill, Philadelphia; Vice-Chairman, Dr. Thomas D. Parke, Birmingham, Ala.; Secretary, Dr. L. T. Royster, Norfolk, Va.; Delegate, Dr. A. C. Cotton, Chicago.

The report as read was adopted and the officers were elected.

Dr. Snyder presented the report of the Executive Committee as follows:

> In compliance with a motion adopted in the Section on the day previous, your Executive Committee held a meeting at 8:30 a. m., June 8, 1910, to take action on the proposed establishment of a special journal devoted to the diseases of children. After unanimously voting approval of the recommendation to the Board of Trustees for the publication of a journal of this nature, the Executive Committee adjourned to meet a committee appointed some time ago by the Board of Trustees to consider the desirability of such a journal, its name, its purposes and scope, manner of publication, etc. At this joint committee meeting it was voted to recommend to the Trustees that the proposed journal be called the *American Journal of the Diseases of Children*. The following recommendations were also adopted: that it should contain original articles and abstracts; that it should contain an occasional complete review. compiled by men appointed by the executive board; that it should begin as a bimonthly of approximately 64 pages in each issue; that it should be of smaller size than the *Archives of Internal Medicine;* that the editors should elect their own chairman; and that the subscription price be determined by the Trustees.
>
> The Russell Sage Foundation, Department of Child-Helping, asks that the Section lend its endorsement to the particular kind of work that this department is carrying on. A feature of this work is the placing of infants from foundling asylums, the training of social workers, etc. Several members of your committee are familiar with the nature and character of this work. The work has been endorsed by the American Pediatric Society. Therefore, the committee would recommend that the Section lend its approval to the work of the Department of Child-Helping, Russell Sage Foundation.

It was moved by Dr. G. R. Pisek, New York, seconded and carried, that the report as read be adopted.

Dr. Samuel W. Kelley, Cleveland, read a paper on "Surgical Mistakes in Practice on Infants and Children." Discussed by Drs. Frank Gengenbach, Denver; John Zahorsky, St. Louis, and S. W. Kelley, St. Louis.

Dr. E. Mather Sill, New York, read a paper entitled "Dietary Studies of Undernourished School Children in New York City." Discussed by Drs. N. R. Coleman, Columbus, Ohio; C. F. Wahrer, Fort Madison, Iowa; C. G. Kerley, New York; S. W. Kelley, Cleveland; G. M. Cattermole, Colorado.

President William H. Welch addressed the Section.

Thursday, June 9—Afternoon

Dr. S. G. Gant, New York, read a paper on "Treatment of Some Colonic, Sigmoidal, Rectal and Anal Affections Common to Infancy and Childhood." Discussed by Drs. L. J. Hirschman, Detroit; C. F. Wahrer, Fort Madison, Iowa; G. S. Hanes, Louisville, Ky.; E. H. Thrailkill, Kansas City, Mo., and S. G. Gant, New York.

Drs. Louis A. Levison and Harry Dachtler, Toledo, Ohio, read a paper on "A Clinical and Roentgenographic Study of the Essential Differences Between the Physical Findings in Childhood and Adult Life." Discussed by Dr. F. Smithies, Ann Arbor, Mich.

Dr. C. F. Wahrer, Fort Madison, Iowa, read a paper on 'Foibles in Specialism." No discussion.

Drs. Eli Long and E. Caldwell, New York, presented a paper on "A Study of the Anatomic Index in Children." Discussed by Drs. Cattermole, Colorado, and Eli Long, New York.

Dr. L. T. Royster, Norfolk, Va., read a paper on "The Prevention of Infant Mortality from an Educational Point of View." Discussed by Dr. S. W. Kelley, Cleveland.

Dr. H. W. Cheney, Chicago, read a paper on "Subnormal Temperature in Infancy." Discussed by Drs. J. S. Leopold, New York; Godfrey R. Pisek, New York; William Butler, Chicago; Frank Gengenbach, Denver, and H. W. Cheney, Chicago.

SECTION ON DERMATOLOGY

Tuesday, June 7—Afternoon

The Section was called to order at 2 p. m. in Odeon Recital Hall by the Chairman, Dr. Grover W. Wende, Buffalo, who delivered an address on "Dermatology in General Practice."

Dr. Frank Crozer Knowles, Philadelphia, read a paper on "Purpura Caused by the Ingestion of the Iodids." Discussed by Drs. Howard Fox, New York; J. A. Fordyce, New York, and F. C. Knowles, Philadelphia.

Dr. Alfred Schalek, Omaha, Neb., read a paper on "Pemphigus Foliaceus. Report of a Case." Discussed by Drs. M. McMahon, Palmyra, Ill.; H. H. Hazen, Washington, D. C.; E. S. Lain, Oklahoma City, and A. Schalek, Omaha, Neb.

Dr. Charles J. White, Boston, read a paper on "Alopecia." Discussed by Drs. William O. Roop, Dayton; Frank C. Knowles, Philadelphia; J. M. King, Nashville; Alfred Schalek, Omaha; J. B. Kessler, Iowa City; Isadore Dyer, New Orleans; M. L. Heidingsfeld, Cincinnati; William Frick, Kansas City; William A. Pusey, Chicago; J. Grindon, St. Louis; J. B. Kessler, Iowa City, Iowa; Frances Rowley, Galveston, Tex., and C. J. White, Boston.

Dr. William Frick, Kansas City, Mo., read a paper on "Dermatitis Exfoliativa." Discussed by Dr. Frank C. Knowles, Philadelphia.

Drs. William T. Corlett and Harold Newton Cole, Cleveland, presented "A Report of Three Epidemics of Anomalous Scarlet Fever." Discussed by Dr. W. L. Baum, Chicago.

The Chairman named the following Nominating Committee: Drs. Charles J. White, W. L. Baum and Howard Fox.

Wednesday, June 8—Morning

This was a clinical meeting.

Dr. R. P. Price, Nevada, Mo., presented two cases of pellagra from the Missouri State Hospital, No. 3. These cases were discussed by Drs. A. Ravogli, Cincinnati; James W. Babcock, Columbia, S. C.; William T. Corlett, Cleveland; J. W. King, Nashville, Tenn., and John D. Long, United States Marine and Public Health Hospital Service, Washington, D. C.

Wednesday, June 8—Afternoon

The following five papers were read and discussed as a Symposium on Cancer:

Dr. Leo Loeb, Philadelphia: "The Present Status of the Etiology of Malignant Growths of the Skin."

Dr. John A. Fordyce, New York: "Pathology of the Malignant Growths of Epithelial Tissue," with lantern-slide demonstrations.

Dr. F. B. Mallory, Boston: "Pathology of Malignant Diseases of Non-Epithelial Formation," with lantern-slide demonstrations.

Dr. Joseph C. Bloodgood, Baltimore: "Surgical Treatment of Cutaneous Malignant Growths."

Dr. William Allen Pusey, Chicago: "Treatment of Malignant Growths of the Skin from a Dermatologic Standpoint."

These five papers were discussed by Drs. E. R. LeCount, Chicago; G. W. Jobling, Chicago; F. B. Mallory, Boston; J. W. Vaughan, Detroit; Willy Meyer, New York; William T. Corlett, Cleveland; A. Ravogli, Cincinnati; J. A. Fordyce, New York; J. C. Bloodgood, Baltimore, and W. A. Pusey, Chicago.

On motion of Dr. Corlett, a vote of thanks was extended to those who had participated in this symposium, and especially to those who were not members of the Section.

On motion the election of officers, scheduled for Thursday morning, was postponed until the afternoon session.

Thursday, June 9—Morning

This was a clinical session.

Dr. George A. Zeller, Superintendent of the State Hospital at Peoria, Ill., presented a number of pellagra cases. Discussed by Drs. James W. Babcock, Columbia, S. C.; Marcus Haase, Memphis, Tenn.; Tinsley Browne, Hamilton, Mo.; Oliver S. Ormsby, Chicago; Howard Fox, New York; Isadore Dyer, New Orleans, and A. J. Vance, Harrison, Ark.

On motion of Dr. William A. Pusey, Chicago, as amended by Dr. M. L. Heidingsfeld, Cincinnati, a vote of thanks was unanimously extended to the Board of Administration of the State of Illinois and to the Board of Governors of the Missouri State Hospital No. 3, at Nevada, Mo., for their kindness and interest in sending a number of pellagra patients to this meeting, where they had afforded unusual opportunity for the study and investigation of this very important subject; also to Drs. Zeller, Lamson, Price and Babcock and others, who had assisted in this valuable presentation.

Thursday, June 9—Afternoon

Dr. James N. Hyde, Chicago, presented a paper on the "Results of Experience with the Noguchi Modification of the Wassermann Serodiagnosis Test for Syphilis," which was read by Dr. J. F. Waugh, Chicago.

Dr. B. C. Corbus, Chicago, read a paper entitled "Two Years' Experience with the Wassermann Reaction in Practice, being a Preliminary Report on Fifty-seven Cases Treated from the Standpoint of the Wassermann Reaction."

These two papers were discussed by Drs. J. Grindon, St. Louis; M. L. Heidingsfeld, Cincinnati; J. A. Fordyce, New York; William Litterer, Nashville, Tenn.; W. T. Corlett, Cleveland; Alfred Schalek, Omaha; E. H. Martin, Hot Springs, Ark.; Edward Bowe, Jacksonville, Ill.; Oliver S. Ormsby, Chicago; V. J. Cohenour, Joliet, Ill.; J. F. Waugh, Chicago, and B. C. Corbus, Chicago.

On recommendation of the Nominating Committee the following officers were elected for the ensuing year: Chairman, James C. White, Boston, Vice-Chairman, Martin F. Engman, St. Louis; Secretary, H. R. Varney, Detroit; Delegate, J. A. Fordyce, New York.

Dr. O. H. Foerster, Milwaukee, read a paper on "Primula Dermatitis." No discussion.

Dr. Marcus Haase, Memphis, read a paper on "A Chronic Itching Papular Eruption of the Axilla, Pubes and Breast." Discussed by Dr. J. A. Fordyce, New York.

Drs. Isadore Dyer and Ralph Hopkins, New Orleans, presented a paper on "The Diagnosis of Leprosy." Discussed by Drs. J. Grindon, St. Louis; A. Ravogli, Cincinnati; Marcus Haase, Memphis; S. T. Darling, Ancon Hospital, Canal Zone; William Litterer, Nashville, and Isadore Dyer, New Orleans.

Dr. Oliver S. Ormsby, Chicago, read a paper on "Lichen Planus Atrophicus (Hallopeau)." No discussion.

Dr. M. L. Heidingsfeld, Cincinnati, presented a paper on "Hairy Tongue," with lantern-slide illustrations. No discussion.

Dr. Richard L. Sutton, Kansas City, Mo., read a paper on "Lichen Nitidus." Discussed by Drs. J. A. Fordyce, New York, and R. L. Sutton, Kansas City, Mo.

On motion of Dr. M. L. Heidingsfeld, Cincinnati, a vote of thanks was extended to the retiring Chairman and to the Secretary for their efficient services; also to the members of the Section living in St. Louis for their kind entertainment, and their efforts which had resulted in making this one of the most successful meetings in the history of this organization.

Friday, June 10—Morning

This was a clinical meeting, devoted to the presentation of patients and specimens.

Dr. R. H. Davis, St. Louis, showed a case for diagnosis, possibly syphilis of the face. No discussion.

Dr. Davis also showed a case of bromid eruption of the leg. Discussed by Drs. Oliver S. Ormsby, Chicago; Frank C. Knowles, Philadelphia; J. M. King, Nashville; Julius Grinker, Chicago; and R. H. Davis, St. Louis.

Dr. Martin F. Engman, St. Louis, showed a case of hypertrophic lupus in a negro boy. No discussion.

Dr. Engman showed a case of blastomycotic dermatitis. Discussed by Drs. A. Ravogli, Cincinnati; J. B. Kessler, Iowa City; John D. Seba, Bland, Mo.; J. M. King, Nashville, and Engman.

Dr. Engman showed a case of keratosis follicularis (Darier). Discussed by Dr. F. C. Knowles, Philadelphia.

Dr. Engman showed a case for diagnosis. Discussed by Drs. Alexander S. Wolf, St. Louis; William T. Cortlett, Cleveland; and H. H. Hazen, Washington.

Dr. Engman showed a case of mycosis fungoides. Discussed by Dr. Howard Fox, New York.

Dr. W. H. Mook, St. Louis, showed a case of epidermolysis bullosa and one of vitiligo. The latter was discussed by Dr. Frank C. Knowles, Philadelphia.

Dr. William W. Graves, St. Louis, showed a number of boys with scaphoid scapula and made some remarks on the subject. Discussed by Drs. A. Jacobi, New York; Ira C. Chase, Fort Worth; Alfred Saenger, Hamburg, Germany; A. Ravogli, Cincinnati; Julius Grinker, Chicago; Albert E. Sterne, Indianapolis; and W. W. Graves, St. Louis.

Dr. R. H. Davis, St. Louis, showed the specimen of a case of congenital ichthyosis.

Drs. Martin F. Engman and W. H. Mook, St. Louis, showed cases of onychia; scleroderma; multiple benign cystic epithelioma; mycosis fungoides; lymphangioma circumscriptum; xanthoma diabeticorum; mycosis fungoides; acne excoriativa; xanthoma planum; and a large papillomatous nevus treated with carbon dioxid snow.

On motion of Dr. William T. Cortlett, Cleveland, a unanimous vote of thanks was extended to the members of the local committee for collecting this valuable clinical material and for the energy shown by the officers of the Section, which had helped to bring this meeting to such a successful close.

SECTION ON PHARMACOLOGY AND THERAPEUTICS

Tuesday, June 7—Morning

The Chairman, Dr. David L. Edsall, Philadelphia, called the meeting to order at 2:30 p. m., in the Delmar Avenue Congregational Church.

Dr. Edsall delivered the Chairman's address, entitled "Some Reforms Accomplished and Others Needed in Pharmacotherapy." No discussion.

Prof. Joseph P. Remington, Philadelphia, delivered the address of Delegates of the American Pharmaceutical Association.

Dr. C. S. N. Hallberg, of Chicago, made a motion that the members of the American Pharmaceutical Association who were delegates and who might not be pharmaceutical members of the American Medical Association might have the privilege of the floor and be invited to participate with the Section of Pharmacology and Therapeutics in the discussion. Seconded and carried.

Reports of Standing Committees were then called for.

The Secretary, Dr. Murray G. Motter, Washington, read the report of the Executive Committee on Habit-Forming Drugs. The report was on motion transmitted to the House of Delegates with the recommendation that it be referred to the Committee on Legislation. [The House referred it to the new Council on Health and Public Instruction. The Journal, June 18, page 2077. The text of the report appears in The Journal, June 18, page 2072.]

Dr. Motter announced that the report of the Committee on United States Pharmacopeia had been published in the reports presented to the House of Delegates. [It appears in The Journal, June 18, page 2088.]

Dr. R. A. Hatcher, New York, Chairman of the Committee, submitted the report of the Committee on National Formulary. Discussed by Drs. F. E. Stewart, Philadelphia; C. S. N. Hallberg, Chicago; A. Jacobi, New York.

On motion, action on the report was deferred until Dr. Hallberg read his paper.

Dr. Edsall, the Chairman, appointed the following substitutes to act as Executive Committee: Drs. R. A. Hatcher, New York; H. M. Whelpley, St. Louis, and W. C. Wescott, Atlantic City, N. J.

Dr. F. E. Stewart, Philadelphia, made a motion, which was seconded and carried, that papers whose authors were absent should be referred to the Executive Committee for recommendation as to whether or not they should be read to the Section.

Dr. C. S. N. Hallberg, Chicago, read a paper entitled "The National Formulary from the Pharmaceutical Standpoint."

Dr. F. E. Stewart, Philadelphia, made a motion that the report of the Committee on National Formulary be adopted and the committee continued, provided the American Pharmaceutical Association Council having control of the Revision of the National Formulary were willing to abide by the rules of the Council on Pharmacy and Chemistry of the American Medical Association. Discussed by Drs. A. S. Loevenhart, Madison, Wis.; A. Jacobi, New York; A. T. Livingston, Jamestown, N. Y.; C. S. N. Hallberg, Chicago; R. A. Hatcher, New York.

A motion by Dr. A. Jacobi, that the report of the committee be accepted and the committee discharged was carried.

The paper of Mr. M. I. Wilbert, Washington, D. C., on "A Forecast of the U. S. P. IX.," was read by Dr. M. G. Motter, Washington, on recommendation of the Executive Committee. Discussed by Drs. A. S. Loevenhart, Madison, Wis.; C. S. N. Hallberg, Chicago, and F. E. Stewart, Philadelphia.

Wednesday, June 8—Morning

The Section held a joint meeting with the Section on Practice of Medicine at the Third Baptist Church.

The Chairman of the Section on Practice of Medicine, Dr. George Blumer, New Haven, Conn., called the meeting to order at 9:30 a. m.

The following four papers were read and discussed as a Symposium on the Circulatory Disorders in Acute Infectious Diseases:

Dr. W. G. MacCallum, New York: "Pathologic Physiology of the Circulatory Failure of Acute Infectious Disease."

Dr. George Dock, New Orleans: "Treatment of the Circulatory Failure of Acute Infectious Diseases with Drugs Other than Alcohol."

Dr. Joseph L. Miller, Chicago: "The Physiologic Action, Uses and Abuses of Alcohol in the Circulatory Disturbances of Acute Infection."

Dr. A. N. Richards, Chicago: "The Action of Alcohol on the Mammalian Heart."

These four papers were discussed by Drs. A. S. Loevenhart, Madison, Wis.; R. C. Cabot, Boston, DeLancey Rochester, Buffalo, N. Y.; J. A. Lichty, Pittsburg; Haven Emerson, New York; G. C. Smith, Boston; A. T. Livingston, Jamestown, N. Y.; G. W. McCaskey, Fort Wayne, Ind.; C. F. Hoover, Cleveland; A. Jacobi, New York; Lawrence Litchfield, Pittsburg; Frank A. Jones, Memphis, Tenn.; B. C. Walt, Little Rock, Ark.; George Dock, New Orleans, and J. L. Miller, Chicago.

This ended the joint meeting.

Dr. Lewis A. Conner, New York, read a paper entitled, "The Visceral Anesthesias of Tabes Dorsalis in Relation to the Diagnosis of Acute Inflammatory Conditions in the Abdomen, with an Illustrative Case." Discussed by Drs. L. Litchfield, *Pittsburg*; J. H. Musser, *Philadelphia*; C. F. Hoover, *Cleveland* and Lewis A. Conner.

Wednesday, June 8—Afternoon

The Section held a joint meeting with the Section on Pathology and Physiology for the consideration of a Symposium on Recent Advances in the Knowledge of Diabetes and its Treatment.

For the minutes see the report of the Section on Pathology and Physiology, which appear on the following page.

Thursday, June 9—Morning

Dr. R. A. Hatcher, New York, presented the report of the Nominating Committee recommending for election the following; Chairman, Dr. Lawrence Litchfield, Pittsburg, Pa.; Vice-Chairman; Dr. George B. Wallace, New York; Secretary, Mr. M. I. Wilbert, Washington, D. C.; Delegate, Dr. Reid Hunt, Washington, D. C.

The report of the Nominating Committee was accepted and the Secretary, Dr. M. G. Motter, was authorized to cast the ballot for the election of the nominees.

Dr. C. S. N. Hallberg, Delegate, reported that he had presented the names of William H. Glover, Lawrence, Mass., and Leonard A. Seltzer, Detroit, for pharmaceutical members of this Section and that both applications had been acted on favorably.

In accordance with instructions, Dr. Hallberg said that he had presented the Report of the Executive Committee to which had been referred the Habit-forming Drugs Legislation and that this report was referred as recommended to the Committee on National Legislation of the A. M. A. He said that when the report of the Reference Committee on National Legislation was made it recommended that the A. M. A. recommend to the states that the state drug laws be made or changed to conform with the federal Food and Drugs Act. Dr. Hallberg, feeling that it was a very serious thing for the Association to go on record as favoring the patterning of the state laws after the federal act, stated that the federal act was a compromise measure which permitted any kind of drugs to be sold, provided that the ingredients were named on the label. At the suggestion of President Welch this recommendation had been amended so that it provided that the Association recommended that drugs must conform with the requirements of the United Pharmacopeia and the National Formulary.

It was moved and carried that the report of the Delegate be accepted.

The following papers were read as a Symposium on Extrapharmacal Methods:

The paper prepared by Dr. C. S. Potts, Philadelphia, on "The Practical Uses of Electricity in Medicine," was read by the Secretary, in conformity with a motion made following the recommendation of the Executive Committee. Discussed by Drs. G. Betton Massey, Philadelphia; David Paulson, Hinsdale, Ill.; A. T. Livingston, Jamestown, N. Y.; H. M. Whelpley, St. Louis, and Haven Emerson, New York.

The paper of Dr. Thomas McCrae, Baltimore, "The Principles of Hydrotherapy," was read by the Secretary. Discussed by Drs. David Paulson, Hinsdale, Ill., and H. M. Whelpley, St. Louis.

On recommendation of the Executive Committee, it was moved, seconded and carried that a paper by Dr. Alfred T. Livingstone, Jamestown, N. Y., not appearing on the program, be read. Dr. A. T. Livingston then read his paper on "The Physiologic Test and Standardization of Ergot." Discussed by Drs. Haven Emerson, New York, and A. T. Livingston, Jamestown, N. Y.

Thursday, June 9—Afternoon

The meeting was called to order in the Delmar Avenue Congregational Church by Dr. Lawrence Litchfield, Pittsburg, Pa., *the Chairman-Elect*, at 2:09 p. m.

Dr. R. A. Hatcher, New York, read a paper written by himself and Dr. Harold C. Bailey, New York, on "The Clinical Use of Strophanthus." Discussed by Drs. J. L. Miller, Chicago; M. Rosewater, Cleveland; L. Litchfield, Pittsburg; H. C. Bailey, New York, and R. A. Hatcher, New York.

Dr. Haven Emerson, New York, read a paper on "Blood Pressure in Tuberculosis." Discussed by Drs. M. Rosewater, Cleveland; J. L. Miller, Chicago; J. M. Bessey, Toledo, Ohio, and Haven Emerson, New York.

In the absence of Dr. James M. Anders, Philadelphia, the Secretary, Dr. M. G. Motter, Washington, D. C., read Dr. Anders' paper on "Vaccines in Typhoid Fever." No discussion.

SECTION ON PATHOLOGY AND PHYSIOLOGY

Tuesday, June 7—Afternoon

The meeting was called to order at 2:10 p. m., in the Lecture Hall of Y. M. C. A. Building, by the Chairman, Dr. H. Gideon Wells, Chicago.

Applications for associate membership in the Section having been received from Professors P. B. Hawk, University of Illinois; A. J. Carlson, University of Chicago; Leo Loeb, University of Pennsylvania; and Graham Lusk, Cornell University Medical School, their names were recommended for presentation to the House of Delegates.

Dr. Carl J. Wiggers, Ann Arbor, Mich., read a paper on "The Prognostic Significance of Pulse-Pressure Changes During Hemorrhage." Discussed by Dr. Yandell Henderson, New Haven, Conn.

Dr. Arthur D. Hirschfelder, Baltimore, read a paper on "The Functional Disturbances in Paroxysmal Tachycardia." Discussed by Drs. S. A. Matthews, Chicago, and A. D. Hirschfelder, Baltimore.

Dr. Robert B. Gibson, Columbia, Mo., read a paper on "The Action of Adrenalin on the Mammalian Heart." Discussed by Drs. C. J. Wiggers, Ann Arbor, Mich.; S. A. Matthews, Chicago; and R. B. Gibson, Columbia, Mo.

Dr. Clyde Brooks, Chicago, read a paper on "The Action of Alcohol on the Normal, Intact, Unanesthetized Animal." Discussed by Drs. Yandell Henderson, New Haven, Conn.; Ida H. Hyde, Lawrence, Kan.; and Clyde Brooks, Chicago.

Dr. C. C. Guthrie, Pittsburg, Pa., read a paper on "Survival of Engrafted Blood-Vessels." No discussion.

Ida H. Hyde, Lawrence, Kan., read a paper on "The Inhibitory Effects of Magnesium Sulphate, and the Nature of the Impulses in the Phrenic Nerves." Discussed by Dr. Louise G. Robinovitch, New York City.

Dr. Angus McLean, Detroit, Mich., read a paper on "Gangrene Following Carbon Monoxid (Coal-Gas) Poisoning." Discussed by Dr. H. G. Wells, Chicago.

The Chairman appointed the following as members of the Nominating Committee: Drs. A. D. Hirschfelder, Baltimore; Henry Albert, Iowa City, Iowa; and E. P. Lyon, St. Louis.

Wednesday, June 8—Morning

Dr. A. S. Warthin, Ann Arbor, Mich., read a paper on "The Reaction of the Hemolymph Nodes to Infection and Intoxication." No discussion.

Dr. Henry Albert, Iowa City, Iowa, read a paper on "Diffuse Hypertrophy of the Mammary Glands of the Female." Discussed by Drs. A. S. Warthin, Ann Arbor, Mich.; James J. Terrill, Galveston, Tex.; Greer Baughman, Richmond, Va.; and Henry Albert, Iowa City, Iowa.

Dr. Arthur E. Hertzler, Kansas City, Mo., read a paper on "The Pathogenesis of Cancer." No discussion.

Dr. Louise G. Robinovitch, New York, read a paper on "Electric Anesthesia and Electric Resuscitation After Heart-Failure Under Chloroform or Electrocution." No discussion.

Drs. H. E. Robertson and A. J. Chesley, Minneapolis, presented a paper on "Pathology and Bacteriology of Anterior Poliomyelitis," which was read by Dr. Robertson. Discussed by Drs. W. H. Welch, Baltimore; and H. E. Robertson, Minneapolis.

Wednesday, June 8—Afternoon

This was a joint meeting with the Section on Pharmacology and Therapeutics.

The following five papers were read and discussed as a Symposium on Recent Advances in Knowledge of Diabetes and Its Treatment:

Dr. Graham Lusk, New York, "Metabolism in Diabetes."

Dr. J. J. R. MacLeod, Cleveland, "Various Forms of Experimental Diabetes and Their Significance for Diabetes Mellitus."

Dr. Joseph H. Pratt, Boston, "The Relation of the Pancreas *to Diabetes.*"

Dr. R. T. Woodyatt, Chicago, "The Action of Glycol Aldehyd and Glycerin in Diabetes, and the Nature of Antiketogenesis."

Dr. George B. Wallace, New York, "Therapy and Dietetics of Diabetes."

These five papers were discussed by Drs. J. M. Allen, Liberty, Mo.; George C. Smith, Boston; J. A. Lichty, Pittsburg, Pa.; J. P. Matthews, Carlinville, Ill.; H. A. Freund, Detroit; Graham Lusk, New York; J. J. R. MacLeod, Cleveland; and R. T. Woodyatt, Chicago.

Thursday, June 9—Morning

The report of the Nominating Committee recommended the election of the following officers: Chairman, Dr. Yandell Henderson, New Haven, Conn.; Secretary, Dr. Leo Loeb, Philadelphia; Delegate, Dr. Walter L. Bierring, Iowa City, Iowa; Alternate, Dr. M. J. Rosenau, Boston. The report of the Nominating Committee was accepted and the Secretary was instructed to cast a ballot for the election of the nominees.

Dr. J. F. Hultgen, Chicago, read a paper on "Influence of Alcohol on the Kidneys." Discussed by Drs. A. S. Warthin, Ann Arbor, Mich.; H. G. Wells, Chicago; Daniel M. Eisendrath, Chicago; and J. F. Hultgen, Chicago.

Drs. Daniel N. Eisendrath and David C. Strauss, Chicago, presented a paper on "Effects of Compression of Its Vessels on the Parenchyma of the Kidney," which was read by Dr. Strauss. Discussed by Drs. V. C. Lespinasse, Chicago; D. N. Eisendrath, Chicago; Yandell Henderson, New Haven, Conn.; H. G. Wells, Chicago; and D. C. Strauss, Chicago.

Dr. Winfield S. Hall, Chicago, read a paper on "The Influence of Diet on the Chyle." Discussed by Drs. J. F. Hultgen, Chicago; and W. S. Hall, Chicago.

Dr. S. A. Matthews, Chicago, read a paper on "One of the Functions of the Duodenum." Discussed by Drs. I. H. Hyde, Lawrence, Kan.; W. C. McCarty, Rochester, Minn.; J. F. Hultgen, Chicago; W. G. McCallum, New York; J. T. Pilcher, Rochester, Minn.; and S. A. Matthews, Chicago.

Dr. William Carpenter McCarty, Rochester, Minn., read a paper on "Classification of Appendicitis, and the Relation of Chronic Appendicitis to Obliteration and Carcinoma (A Study of 5,000 Specimens Removed at Operation)." Discussed by Drs. J. F. Hultgen, Chicago; H. G. Wells, Chicago; and W. C. McCarty, Rochester, Minn.

Thursday, June 9—Afternoon

The following five papers were read and discussed as a Symposium on the Progress in the Problems of Cancer:

Dr. Leo Loeb, Philadelphia, "Recent Progress and Present Status of Experimental Research in Cancer."

Dr. E. E. Tyzzer, Boston, "The Relation of Heredity to Cancer."

Dr. Richard Weil, New York, "The Biochemical Investigations of Cancer, and Its Diagnostic Applications."

Dr. F. B. Mallory, Boston, "Recent Progress in the Microscopic Anatomy and Differentiation of Cancer."

Dr. J. C. Bloodgood, Baltimore, "Recent Progress in Surgical Treatment of Malignant Growths."

These five papers were discussed by Drs. Louis B. Wilson, Rochester, Minn.; F. B. Mallory, Boston; and H. Gideon Wells, Chicago.

THE ST. LOUIS REGISTRATION

List of Members Who Registered at the St. Louis Session, June, 1910

The total registration at the St. Louis session was 4,084, an increase of 812 over last year's registration at Atlantic City. This is the third session in point of size.

In addition to the names of members given below, a number registered whose names are not given. These have not yet completed their membership, many having been subscribers only and some of them claiming membership without making application, as is required by the Constitution and By-Laws.

Below are given two summaries, one by sections and one by states.

REGISTRATION BY SECTIONS

Practice of Medicine	1,389
Obstetrics and Diseases of Women	296
Surgery	1,124
Ophthalmology	275
Laryngology and Otology	167
Nervous and Mental Diseases	110
Preventive Medicine and Public Health	95
Stomatology	55
Diseases of Children	157
Dermatology	84
Pharmacology and Therapeutics	42
Pathology and Physiology	66
Registered without specifying any one section	105

REGISTRATION BY STATES

Alabama	22	Nebraska	37
Arizona	2	New Hampshire	3
Arkansas	97	New Jersey	20
California	38	New Mexico	6
Canal Zone	3	New York	149
Colorado	38	North Carolina	11

Simple Syrup in the Treatment of Wounds.—Renssen noticed that the workmen in sugar factories applied syrup in treatment of wounds, and this suggested that the syrupy consistency might be responsible for the good effects of balsam of Peru in the treatment of wounds. He was confirmed in this impression by the fact that equally good results are obtained with pure and adulterated balsam. A letter from Holland in the *Wiener klin. Rundschau*, April 3, states that Renssen has applied the simple syrup in 60 cases of various injuries, including compound fractures, and found that the lesions healed remarkably promptly and well. One very agreeable feature of the syrup treatment is that it can be washed off so readily.

Medical Education and State Boards of Registration

COMING EXAMINATIONS

ALABAMA: Montgomery, July 12. Chairman, Dr. W. H. Sanders.

ARIZONA: Phoenix, July 5-6. Sec., Dr. Ancil Martin.

COLORADO: Denver, July 5. Sec., Dr. S. D. Van Meter, 1723 Tremont Street.

CONNECTICUT: Regular, City Hall, New Haven, July 12-13. Sec., Dr. Charles A. Tuttle; Homeopathic, New Haven, July 12. Sec., Dr. Edwin C. M. Hall, 82 Grand Ave.; Eclectic, New Haven, July 12. Sec., Dr. T. S. Hodge, 19 Main Street, Torrington.

DISTRICT OF COLUMBIA: Washington, July 12-15. Sec., Dr. George C. Ober, 125 B Street, S. E.

INDIANA: Room 120, State House, Indianapolis, July 12-14. Sec., Dr. W. T. Gott.

KENTUCKY: Louisville, July 5-7. Sec., Dr. J. N. McCormack, Bowling Green.

MAINE: Augusta, July 19-20. Sec., Dr. F. W. Searle, Portland.

MASSACHUSETTS: State House, Boston, July 12-14. Sec., Dr. Edwin B. Harvey.

NEW HAMPSHIRE: Concord, July 6-7. Regent, Mr. H. C. Morrison.

NORTH DAKOTA: Grand Forks, July 5-7. Sec., Dr. H. M. Wheeler.

OKLAHOMA: Ione Hotel, Guthrie, July 12. Sec., Dr. Frank P. Davis, Enid.

RHODE ISLAND: State House, Providence, July 7-8. Sec., Dr. Gardner T. Swarts, 315 State House.

SOUTH DAKOTA: Lead, July 13-14. Sec., Dr. F. W. Freyberg, Mitchell.

UTAH: Salt Lake City, July 4-5. Sec., Dr. G. F. Harding, 310 Templeton Building.

VERMONT: Burlington, July 12-14. Sec., Dr. W. Scott Nay, Underhill.

WASHINGTON: Seattle, July 5. Sec., Dr. J. Clinton McFadden, People's Bank Building.

WEST VIRGINIA: Capitol Bldg., Charleston, July 11-13. Sec., Dr. H. A. Barbee, Point Pleasant.

WISCONSIN: Madison, July 12-15. Sec., Dr. John M. Beffel, 3200 Clybourn Street, Milwaukee.

Rhode Island April Report

Dr. Gardner T. Swarts, secretary of the Rhode Island State Board of Health, reports the written examination held at Providence, April 7-8, 1910. The number of subjects examined in was 7; total number of questions asked, 70; percentage required to pass, 80. The total number of candidates examined was 9, of whom 4 passed and 5 failed. The following colleges were represented:

College	Year Grad.	Per Cent.
PASSED		
Yale Medical School	(1907)	91.7
College of Physicians and Surgeons, Baltimore	(1909)	80.0
Columbia University, Coll. of Phys. and Surg.	(1908)	87.8
Albany Medical College	(1904)	91.8
FAILED		
Georgetown University	(1900)	71.9
Baltimore Medical College	(1909)	75.2
University College of Medicine, Richmond	(1907)	71.1
Laval University, Quebec	(1904) 55.4; (1909)	66.9

Arizona April Report

Dr. Ancil Martin, secretary of the Board of Medical Examiners of Arizona, reports the written examination held at Phoenix, April 4-5, 1910. The number of subjects examined in was 9; total number of questions asked, 90; percentage required to pass, 75. The total number of candidates examined was 7, of whom 4 passed and 3 failed. The following colleges were represented:

College	Year Grad.	Per Cent.
PASSED		
College of Physicians and Surgeons, Los Angeles	(1909)	84
University of Louisville	(1909)	75
Medico-Chirurgical College, Philadelphia	(1896)	81
Memphis Hospital Medical College	(1901)	79.2
FAILED		
Hospital College of Medicine, Louisville	(1897)	66.5
Omaha Medical College	(1896)	62.8
University of Tennessee	(1901)	56.8

Utah April Report

Dr. G. F. Harding, secretary of the Utah State Board of Medical Examiners, reports the written examination held at Salt Lake City, April 4-5, 1910. The number of subjects examined in was 16; total number of questions asked, 100; percentage required to pass, 75. The total number of candidates examined was 4, of whom 3 passed and 1 failed. One candidate was licensed through reciprocity. The following colleges were represented:

College	Year Grad.	Per Cent.
PASSED		
Rush Medical College	(1907)	91.8
Northwestern University Medical School	(1909)	82.9
Woman's Medical College of Pennsylvania	(1907)	87.9
FAILED		
Keokuk Medical College, Coll. of Phys. and Surg.	(1905)	68.8

LICENSED THROUGH RECIPROCITY

College	Year Grad.	Reciprocity with
Northwestern University Medical School	(1908)	Illinois

Maine March Report

Dr. Frank W. Searle, secretary of the Maine Board of Registration of Medicine, reports the written examination held at Portland, March 8-9, 1910. The number of subjects examined in was 10; total *number of questions asked, 90; percentage* required to pass, 75. The total number of candidates examined was 8, of whom 7 passed and 1 failed. One candidate was *licensed through reciprocity. The following colleges were* represented:

College	Year Grad.	Per Cent.
PASSED		
Baltimore Medical College	(1905)	83
Boston University	(1893)	75.6
Tufts College Medical School	(1907) 91.4; (1909)	78.6
Harvard University Medical School	(1899)	85
Laval University, Quebec	(1908) 75.5; (1909)	83.2
FAILED		
Laval University, Quebec	(1908)	70.8

LICENSED THROUGH RECIPROCITY

College	Year Grad.	Reciprocity with
University of Michigan, College of Medicine	(1909)	Michigan

Massachusetts March Report

Dr. E. B. Harvey, secretary of the Massachusetts Board of Registration in Medicine, reports the written examination held at the State House, Boston, March 8-10, 1910. The number of subjects examined in was 13; total number of questions asked, 70; percentage required to pass, 75. The total number of candidates examined was 74, of whom 37 passed, including 3 osteopaths *and 36 failed, including 3 osteopaths and* 10 non-graduates. One candidate did not complete the examination. The following colleges were represented:

College	Year Grad.	Per Cent.
PASSED		
Medical School of Maine	(1884) 75; (1907)	79.7
College of Physicians and Surgeons, Baltimore	(1909)	76.6
College of Physicians and Surgeons, *Boston*	(1908)	80.2
Boston University	*(1882) 79.3; (1909)*	75
Harvard Medical School	*(1907) 75; (1908) 78.4, 79.5; (1910)*	75.9, 82.2.

Medical Economics

THIS DEPARTMENT EMBODIES THE SUBJECTS OF ORGANIZATION, POSTGRADUATE WORK, CONTRACT PRACTICE, INSURANCE FEES, LEGISLATION, ETC.

The Opposition to a Department of Health

Last week, in the Correspondence Department, we published a letter sent to the newspapers by Prof. Irving Fisher, in behalf of the Committee of One Hundred on National Health. In that letter a reference was made to Bulletin 41 of the Committee of One Hundred. This bulletin is so good that we reproduce below the major portion of it:

COMMERCIAL INTERESTS OPPOSE NATIONAL DEPARTMENT OF HEALTH

Judge Lindsey, in his famous articles on "The Beast in the Jungle," has shown how human life and child welfare are ruthlessly sacrificed to commercial interests. The same is true on a far broader scale. One cannot touch the problem of public health at any point without encountering the opposition of commercial interests. The old efforts of the merchants of San Francisco to suppress the news of bubonic plague, and of the merchants in southern states to suppress the knowledge of yellow fever, are classical instances. But those who are familiar with health work run into such instances repeatedly. Dr. Wiley pointed out at the congressional hearing in favor of the Owen bill for a department of health that a health officer cannot develop properly unless he is in an environment in which health is the main interest. It is small wonder that the commercial interests do not want an independent department of health. They feel safer with a bureau of health, located in a department devoted to commercial interests. Our principal health bureau is now located in the Department of the Treasury, which is—as it should be—more devoted to financial than to hygienic considerations. Our next important health bureau is that which dispenses the Food and Drugs Act in the Department of Agriculture, which is *another commercial* department. The plans for transferring the health bureaus to any other of the existing departments, such as the Department of Commerce and Labor or the Department of the Interior, also have the weakness that these departments are dominated by commercial interests.

"THE BEAST IN THE JUNGLE"

Judge Lindsey is not the only one who has seen the "Beast in the Jungle." The advocates of the Owen Bill to establish a national department of health have suddenly encountered in their jungle a wolf in sheep's clothing. As in Judge Lindsey's article, at first the "beast" is not visible, but instead some very respectable, but misguided, people appear on the scene as officers of and sponsors for a so-called "National League for Medical Freedom."

This "League" has organized opposition to the establishment of a national department of health, large advertisements having recently appeared in New York, Washington, and other newspapers, although they have been taken as a joke in and out of Congress. The advertisement tries to create the impression that the movement is one of a "medical trust," attempting to control the practice of medicine. Mr. Charles W. Miller, an Iowa State representative, has been in Washington trying to bring influence to bear on congressmen. Mr. B. O. Flower, a Christian Scientist editor, is president of the League.

They seem to have overlooked the fact that the federal government has no power to regulate the practice of medicine, or to restrict medical freedom, even if this were intended, which it is not.

Previous to the appearance of this wide-spread and expensive advertising, Mr. Miller had been loudly stating that the movement for a department of health had no strength. Why, then, the need of so much effort to combat it? It is estimated that their advertisements are costing somebody $25,000 a day. At this rate, in two or three days they spend more than the American Health League, which has been a potent factor in the movement for the establishment of a national department of health, has spent in the three years of its existence. The same Mr. Miller has criticised the Committee of One Hundred on National Health, which forms the nucleus of the American Health League, for trying to raise a campaign fund, and for suggesting that the government should spend more money on public health. The expenditures of Mr. Miller's "League" not only greatly exceed ours, but include three items which we have never included among our expenditures: viz., for the purchase of newspaper space, for the purchase of articles, and for the purchase of the services of legal representatives to appear at the congressional hearings.

The league for "Medical Freedom" is said to consist of Christian Scientists, osteopathists, homeopathists, eclectics and antivivisectionists. The advertisements state that to join the league no fee is required. Yet they are able to carry on an immensely expensive campaign. Are they willing to state the sources of their income? Simultaneously with the formation of the league, health writers have been approached and offered large sums of money to write against the Owen Bill for establishing a department of health. One writer refused what he believed was an opportunity to make two thousand dollars in this way.

TAX PAYERS' LEAGUE

This attack from the "National League for Medical Freedom" has such a family resemblance to various other attacks, on a smaller scale, which have appeared during the last few years, that we have rummaged through our files for the sake of comparison.

Like Lindsey's "beast," ours seems to have made its first appearance in Denver. The first among our curiosities of "medical" literature was a venomous pamphlet by a notorious quack of Denver, and purporting to represent the "Colorado Medical Liberty League, an organization numbering 1,300 enrolled members who are tax-paying citizens."

This title bears a striking resemblance to the "National League for Medical Freedom" and its associated tax payers' leagues, which have at the same time, and within a few days of each other, been "organized" in a dozen or more states. While nominally written by a "drugless" doctor, this pamphlet singles out for attack those men and magazines, such as *Collier's* and the *Ladies' Home Journal*, that have fought quackery and the "patent-medicine" evil, and have championed the pure food law.

The following quotations show its animus against pure foods and drugs:

> *Question:* What is the attitude of the Committee of One Hundred in regard to the adulteration of food stuffs and the substitution of drugs as commonly practiced by many commercial concerns?
>
> *Answer:* It is against all concerns that do not give the finance committee a rake-off.
>
> *Question:* What is the attitude of the Committee of One Hundred towards injurious "patent-medicines?"
>
> *Answer:* It is dead set against all patents which do not contribute to the trust's pocket.
>
> *Question:* Do any members of the Committee of One Hundred receive salaries or other remuneration?
>
> *Answer:* Nay, nay, that would spoil our game. They will be taken care of later.
>
> *Question:* How can additional information, including printed matter issued by the Committee of One Hundred, be obtained?
>
> *Answer:* In car lots or less, F. O. B., New Haven, Conn.
>
> *Question:* What are the publications and pamphlets now or formerly distributed by the Committee of One Hundred?
>
> *Answer:* They are too numerous to mention—mostly devoted to "exposing" quacks. A quack is any one who is not orthodox according to the dictum of the medical trust.
>
> *Question:* Why must an organization of citizens be formed to protect the public health?
>
> *Answer:* Because that is the only way we can fool the suckers into continuing to take patent medicines only as doctor's prescriptions.

This pamphlet refers to the American Medical Association as a "trust," and composed of "old school fanatics," takes sides with eclectics, osteopathists, spiritual healers, etc., and ends with the following statement: "If the public does not want to be bulldozed by the medical trust, it will at once file its protest against a national bureau of medicine by writing individual letters to congressmen, promising to vote out of office all who vote for such a bureau."

In his speech before the Senate, May 25, Senator Owen said:

> I am informed that the sudd[illegible] interest of the "taxpayers and voters" of the [illegible] are organized in this artificial manner and the [illegible] or manifested of the "homeopaths" and of the [illegible] the "eclectics" and of the great variety of those who have special views with regard to the various methods of healing the sick has taken place

within seven days, and like a flash of lightning telegrams are coming in from Maine to California. The chairman of the Committee on Public Health and National Quarantine of the Senate received a very large number of them. Such sudden universality of disapproval of a department of public health on such an unsound theory is astounding; it is more, it is extremely suspicious; it is obviously artificial; it is perfectly apparent that somebody is spending a very large amount of money on this sudden propaganda; it can hardly be doubted that somebody, in gross error, is advising the "homeopaths," the "osteopaths," the "eclectics" that their right to practice medicine is about to be invaded by the federal government.

THE NATURE OF OUR OPPOSITION

Another pamphlet is entitled, "The Political Doctors' Slick Little Joke,—On Congress, on the States, the Pure Food and Drugs Act, and the People." The writer attempted to establish the thesis that the Committee of One Hundred is the tool of the American Medical Association and of the Catholic Church! He quotes scripture to prove this. He distributed a sizeable booklet entitled "Roosevelt Steam-Rolled by the Bible." He shows that the Committee of One Hundred on National Health was prophesied in the Bible and that the "medical arm of papacy is really the pivot on which the old earth of error is to swing into the new heaven and new earth of revelation." In a letter in reference to his book he says, "You may be surprised to know that Taft can be identified in the Bible in more places than the place indicated in my book—the other places are not yet made public. The subleties of the science of medicine and of philosophy are to be confronted by the subleties of the Bible."

The author of these curious aberrations of mind adds in a postscript, "I want to say if you have any intention of getting me committed to the Government Hospital for Insane, you will be foiled."

This insane literature seems of a piece with the literature of the "National League for Medical Freedom." But now these people seem to have found a barrel of money with which they are "moulding" public opinion. It is easy to understand how quacks and nostrum vendors may object to the national pure food law which they are seeking by every means to undo; but it is sad to see reputable and earnest men unwittingly made tools of, and still sadder to see other reputable men sell their services as paid attorneys, and to see writers—unconsciously though it be—prostitute their abilities in the interest of those vampires who feed on illness and prey on the public health.

"LICENSE THEY MEAN, WHEN LIBERTY THEY CRY"

The New York *Times*, which made the mistake on May 17 of printing the advertisement of the "League for Medical Freedom," corrected it on the 18th by the following strong editorial:

"Medical Freedom"

> Makers of "patent medicines," adulterators of drugs, and practitioners of the cults of mental and osteopathic healing are up in arms. They have persuaded a few well-intentioned but misled individuals to join them, and have formed the "National League for Medical Freedom" to oppose the efforts of practically all the reputable physicians in the country to consolidate the agencies of public health at Washington into one efficient department or bureau.
>
> These efforts have been waxing stronger. The men of the American Medical Association and of the Committee of One Hundred on National Health, sanctioned by the Association for the Advancement of Science and headed by Prof. Irving Fisher of Yale, have won the approval of the entire press of the United States in urging the passage of their bill. In the various departments and bureaus of the federal government are lodged powers that cannot be wielded effectively until they shall be coordinated under one head. Once united, they can be used in a great propaganda for educating the people against the habit of self-dosage and a resort to quack medicines for their ailments. By a campaign of prevention the bureau would break the prevalence of epidemics and infections between the states. It would work for the passage of laws that would guard the channels of interstate commerce against the admission of adulterated drugs, and for the establishment of standards of purity and strength that would be copied by the states and cities of the nation.
>
> The self-styled "League for Medical Freedom" quotes Professor Fisher accusingly as having said that the government might soon be appropriating millions yearly for the conduct of this bureau. If it should appropriate a million for every hundred thousand it now appropriates for the protection of the health of hogs and of cattle in the United States, Professor Fisher's prophecy would be fulfilled, and no one would have cause for complaint but these friends of "freedom." Their cry is an old one and well understood.
>
> "License they mean, when liberty they cry."

WHENCE COME THE FUNDS?

The opinion expressed in this editorial is general. It is fair to say that the well-intentioned leaders in this League for "Medical Freedom" doubtless do not realize the situation in which they are placed. They may be correct in their denial that their "League" is being financed by "patent-medicine" interests, but they have not yet disclosed specifically the sources of their funds. Requests so to do have thus far been unanswered. From appearances they have spent more in one day than our committee has spent in a year.

Whatever the source of their funds there can be no doubt that a virtual alliance exists between this league and the purveyors of "patent-medicines" and the opponents of the pure food law.

On the advisory board of the new league is the editor of the organ of the National Association of Retail Druggists, controlled by the members of the "American Druggists' Syndicate" or the "drug trust," which has been so hand-in-glove with the quack medicine interests that many hundreds of its members resigned last fall in protest.

A congressman, on looking up the occupations of the signers of telegrams against the Owen Bill, found a liberal sprinkling of "patent-medicine" proprietors and vendors.

In this unholy and anomalous alliance between "Christian Scientists" and quack medicines are included the services of some newspapers that rely for revenue on quack advertising. (See our bulletin on "A Century's Criminal Alliance Between Quacks and Some Newspapers," by C. S. Andrews).

COINCIDENCES

It may be a coincidence, but simultaneously with the appearance of this "league" in Washington, the same lobbyists who had fought the pure food law also appeared, although not publicly. It may also be a coincidence that at about the same time a certain noted writer on health was offered a large sum of money to write articles to "kill the Owen Bill." Those who approached him for this purpose reluctantly admitted, after first alleging that they represented Christian Scientists, etc., that the "patent-medicine" interests were also behind them.

It may also be a coincidence that one of these afterward acted as an agent to place the advertisement of the "League for Medical Freedom."

It may also be a coincidence that this vigorous effort to prevent the creation of a department of health began immediately after the issue by the Department of Agriculture of a bulletin by Dr. Keber against nostrums, in which—for the first time in history—the names of the "remedies" to be avoided were printed. It would not be strange if the firms that were thus hit hard by the Department of Agriculture should not want to be hit harder, as they might be and ought to be, by a department of health.

It may be a coincidence that at this same time a newspaper now actively opposing a National Department of Health sent a reporter to one of the officers of the Committee of One Hundred to inquire what the committee expected the new department of health to do, and whether, perchance, the committee knew of the nostrum report just made.

It may also be a coincidence that a chemist, interested in food adulteration, came at almost the same time to ask almost the same question.

MISCONSTRUCTION OF FACTS TO MISLEAD READERS

The eagerness of those who construct these advertisements to mislead is illustrated in many ways. For instance, they have utilized a misprint in the report of one of the hearings as follows:

> *Question:* What is the Committee of One Hundred?
>
> *Answer:* One of its members, Hiram J. Messenger, when asked this question by Senator Crawford of South Dakota (Senate Hearing Owen Bill Page 30) stated, "The Committee of One Hundred is a committee that was appointed by the American Medical Association for the Advancement of Science."

The word "medical" was obviously a slip of the tongue or of the pen. No one ever pretended before that there was any connection between the American Medical Association and the American Association for the Advancement of Science!

MEDICAL CULTS

"The League for Medical Freedom" does not seem to really represent the leading members of the schools of medicine they claim to represent. The foremost members of these various cults have openly favored the Owen Bill. Dr. J. B. Gregg Custis, a homeopath who spoke in favor of the bill, is chairman of the Board of Medical Examiners of the District of Columbia and ex-president of the American Institute of Homeopathy as well as of the International Congress of Homeopathy. Mr. George H. Shibley, a prominent lawyer of Washington, whose wife is an Osteopathist practitioner and who is himself the attorney of this system of healing before committees of Congress, favored the bill and among other things said:

> As a citizen and a lawyer, I am deeply interested in the establishment of a national health department. *Possibly I can help to dispel some of the fears of those who, in other ways, have come into conflict with the American Medical Association.*
>
> There is no possible way whereby any medical sect can secure national health regulations that will interfere with the states'

control of the licensing of the competing schools of healing. It follows that the osteopathic physicians, the homeopathic physicians and the eclectic physicians are in no danger from a national health department.

REAL PURPOSE OF DEPARTMENT OF HEALTH

A department of health has really nothing to do with the medical art. It is really for the purpose of preventing diseases by preventing the pollution of streams, by preventing the adulteration of foods, by preventing the importation of bubonic plague and yellow fever, by investigating health conditions and disseminating information. It has been proved that there are over half a million premature deaths yearly in this country. The Owen Bill, if passed, would ultimately prevent a large proportion of these.

From Owen's Senate Speech: As the author of this bill I wish to say that I believe the more a man knows about the laws of health the less drugs he takes. I have employed homeopaths and osteopaths and allopaths as well to treat myself and the members of my family. I have studied the doctrine of suggestive therapeutics and of Christian Science with great interest and respect, and cordially indorse Horace Fletcher as the best doctor of them all. I stand firmly for medical freedom and for the right of the citizen to select his own medical or spiritual adviser.

THOSE WHO WANT A DEPARTMENT OF HEALTH

The principle of the Owen Bill, establishing a department of health, has been endorsed by the President of the United States, by the surgeon-generals of the Army, of the Navy, and of the Public Health and Marine-Hospital Service, by Dr. H. W. Wiley of the Bureau of Chemistry, by the governors of states, by the Conference of State and Territorial Boards of Health, by the American Medical Association, by the American Public Health Association, by the United Mine Workers of America, by the National Grange, by the Republican and Democratic platforms, and by numerous other organizations.

Life-insurance companies, who advocate this bill, certainly have no desire to limit medical freedom and repress any system which offers the chance of lengthening human life. They have no medical partisanship, and their sole interest is to lengthen life by whatever means possible. Their actuaries state specifically that they believe human life could and would be lengthened by the establishment of a health department.

GENERAL WYMAN FAVORS DEPARTMENT

At the May 19th hearing on the Owen Bill, General Walter Wyman, Surgeon-General of the Public Health and Marine-Hospital Service, came out strongly and firmly in favor of establishing a national department of health. General Wyman has hitherto been non-commital, and the opinion had been entertained generally that he was opposed to the measure.

THE "MEDICAL TRUST"

The American Medical Association has trod on many toes in its efforts to get state legislation enacted. It is natural that enemies thus made should strike back. But in attacking national legislation they are "barking up the wrong tree." Moreover, a great injustice is being done the American Medical Association. It is not a "trust." No one will deny that it includes in its membership the best and ablest men in the profession. It has tended to liberalize rather than to narrow medical ethics and practice. While it has aimed at restrictions, the object has been to prevent the vicious and harmful quack and charlatan from plying his nefarious trade. Naturally it is not infallible, and has doubtless made mistakes, but the present attack on it will be resented by the large public who appreciate the work of the medical profession, as well as by all who believe in fair play.

AMERICAN HEALTH LEAGUE MEMBERS SHOULD HELP

It is important that every member of the American Health League should know that a fight is on. Against us are arrayed the leagues of "freedom," the quack medicine interests, the newspapers allied (by advertising) therewith, and the able attorneys and editors they employ. On our side are President Taft, ex-President Roosevelt, political party platforms, medical, hygienic, scientific, educational, philanthropic, insurance, labor, and grange organizations. While intrinsically we have infinitely the stronger side, our enemies have the great advantage of money. The situation is as serious as in a political campaign in which the forces of evil and money so often triumph. It is another case of the people against the special interests. Each loyal member of our league, and each loyal citizen who reads these lines, should do his part, namely, contribute, if possible, to the expenses of conducting this campaign for establishing a national department of health, and write to congressmen urging their favorable consideration of the Owen Bill

Medicolegal

Requirements and Rights of Applicants for Examination—Power of State Board to Determine What Are Reputable Medical Colleges

The Supreme Court of Missouri says, in the case of State, on the relation of Abbott and others, vs. Adcock and others, constituting the State Board of Health (124 S. W. R. 1100), that a reading of Section 1 of an act approved April 4, 1907, shows that it requires three things of each applicant who desires to be examined touching his qualifications to practice medicine and surgery in Missouri: First, that he shall make application in writing to the secretary of the board 30 days before the meeting thereof; second, that he furnish to the board satisfactory evidence of his scholastic qualifications as therein provided for; and, third, that he shall also furnish to the board satisfactory evidence of having received a diploma from some reputable medical college of four years' requirements at the time of his graduation.

While the act mentioned does not undertake to state what medical colleges are or what are not reputable within the meaning thereof, by clear implication it leaves that question for the determination of the Board of Health. This is made manifest by the act requiring the proof of reputableness to be furnished to the board when the applicant presents himself for examination, and by withholding from the board the authority to issue the license until such satisfactory evidence is furnished. In the court's opinion the language of this act is susceptible of no other construction than that it placed the burden on the relators, when they presented themselves for examination before the board, to prove to its satisfaction by satisfactory evidence the reputableness of Barnes University, and especially the medical department thereof.

If the court correctly understands the position of counsel for the relators, they did not controvert the soundness of the conclusions above stated, but contended that, under the laws of Missouri, "the State Board of Health has no authority to adopt and promulgate fixed rules and regulations as the standard by which the various medical colleges of this state will be adjudged reputable or non-reputable within the meaning of the statute relating to the practice of medicine and surgery. The word 'reputable,' as applied to medical colleges, means reputation, and must be proved in the same way." But, in the court's opinion, counsel misconceived the meaning and object of the rules and regulations adopted by the Board of Health fixing the standards by which various medical colleges would be adjudged reputable within the meaning of the act under consideration. The rule simply provides that all medical colleges, wherever located (and not simply those situate in Missouri), which should, on or before Oct. 1, 1907, conform to the standards specified in the schedule of minimum requirements adopted by the board on July 11, 1907, "should be rated and classified as accredited and reputable, and whose students, after being graduated therefrom, should be admitted to the examination of the State Board of Health for licenses to practice medicine and surgery in the state of Missouri," without being required to furnish other proofs of reputableness, and thereby save each of them the time and expense of furnishing the proofs required of them by said act. In other words, the board, by such rules, undertook to require all medical colleges to adopt such standards as would establish and prove their reputableness in all cases, and thereby remove those burdens from each student who applied for a license, as provided by said act. But said rules of the board do not provide that no graduate from any medical college which has not conformed to those requirements shall not be examined touching his qualifications to practice said professions. This construction seems to have been adopted subsequent to the origin of this controversy. Neither rule nor board is responsible for it.

In the court's opinion, since the act left it to the board to pass on the reputableness of all medical colleges whose graduates applied to it for examination, and to determine the character of the evidence by which said fact was to be established, said rules were not only reasonable and just, but were also wise and proper. All medical colleges and their students were thereby notified in advance as to what would satisfy the board as to the reputableness of each college. The diploma alone from all colleges which had adopted those standards would entitle the holder thereof to take the examination without further ado. Otherwise many students might innocently be induced to attend colleges which were not, in fact, reputable, and consequently such students would thereby be prevented from establishing their reputableness. In all such cases a great hardship would be visited on all such graduates, but under these rules of the board no injustice could be done to any college or graduate thereof. And, beyond that, the adoption of said standards by the board, and the direct tendency thereof, if the colleges will only conform thereto, would be to uplift and better medical instruction, place her institutions of learning on a higher plane, and reduce the practice of medicine and surgery to a more perfect science, all of which would result in great good to suffering humanity.

But suppose, for argument's sake, that the court is in error in its views regarding the meaning and object of the rules of the board establishing said standards, and that it was the intention of the board to thereby notify, in advance, all persons who might present themselves for examination for licenses to practice medicine and surgery that it would examine no one except those who presented a diploma from some one of the medical colleges which had adopted said standards. That would not excuse the applicant for examination from tendering to the board such evidence as he might have tending to prove that his alma mater was a reputable school within the meaning of the statute. The rule would be illegal and void, and would constitute no legal bar to the applicant's right to stand the examination for his license. Nor could the adoption of such a rule be construed to mean that the board had thereby refused to examine a particular person for a license to practice medicine. The board might change its mind before the date fixed arrived, and before being called on to act. As long as a man or a body of men fill any official position, the law presumes he or they will perform his or their duties whenever any matter is legally presented for action, notwithstanding general declarations previously made to the contrary.

If the relators possess the necessary scholastic attainments and diplomas from some reputable college, and if they can produce before the Board of Health satisfactory evidence of the reputableness of said college, then doubtless the board will, on proper request, give them an examination, as provided for by the act of 1907, and, if found qualified, will presumably issue to them licenses. But if, after such showing, the board should unjustly and arbitrarily refuse to examine them, it would then be time enough to institute mandamus proceedings to compel it to act.

Validity of Note Given for Medical Services to Unlicensed Person

The Appellate Court of Indiana, Division No. 1, says, in Hill vs. Ward (91 N. E. R. 38), a suit on a note made payable to one Doremus and transferred before maturity by indorsement, that a good defense was stated by allegations that the note was given for medical services rendered by a person who was not entitled to receive pay for such services. The Indiana statutes make it a misdemeanor for any person to practice medicine without a license duly issued under the laws prescribed. This being true, the act of Doremus in treating the defendant was an illegal act, and the receipt of the note for such services was a part of such illegal act. It is a well-settled rule of law that business transactions in violation of law, or which involve the commission of a crime or misdemeanor, cannot be made the foundation of a valid contract, and any contract so made is void, and a recovery for services thereunder cannot be had. Cooper, Adm'r, vs. Griffin, 13 Ind. App. 212; Orr vs. Meek, 111 Ind. 40. The cases cited apply the rule to the right to recover for services in the practice of medicine without a license. So the averment showing that the note was given as a part of an illegal contract was a sufficient answer to the complaint, and put the burden on the plaintiff to show his right to recover, notwithstanding the illegality in its execution.

7 *Cardiac Syphilis. G. G. Sears, Boston.
8 *Treatment of Inebriety. I. H. Neff, Foxborough, Mass.
9 *Tuberculous Peritonitis. A. E. Stone, Boston.

7. **Cardiac Syphilis.**—Sears believes that a noteworthy percentage of the patients die suddenly without previous manifestations of ill health, and that numerous others are conscious of little or no cardiac disturbance until a period of overwork or possibly some special effort, which often seems no greater than what they have been accustomed to make without discomfort, leads to an upset of the cardiac balance, with a rapid development or even an immediate onset of urgent symptoms. This may be shown by an attack of which tachycardia accompanied by great anxiety and mental distress is the most striking symptom, or by the usual signs of myocardial insufficiency, dyspnea, precordial discomfort, etc., which may be soon followed by general passive congestion, edema and ascites. Severe headache and vomiting are not uncommon early symptoms. A striking peculiarity of many of these cases has been the lack of response to rest and cardiac stimulants in spite of the fact that one is dealing with the first breakdown. While a certain amount of relief may be obtained, results are often disappointing. Relapses easily occur from what seem inadequate causes.

8. **Treatment of Inebriety.**—Based on the examination of 700 cases of inebriety, Neff claims that inebriety is an expression of nervous weakness or nervous instability; used in its simplest sense it could be called a psychoneurosis, many cases showing symptoms which are found in neurasthenic states and allied conditions. Addiction to alcohol is a symptom of an unstable nervous system, and the contrary view expressed by the laity is not justified by clinical observation or experience. The exciting causes of inebriety, he says, are of physical and psychologic origin. Given a neurotic subject, crises may be precipitated by any marked departure from the ordinary routine (psychologic) or by any disturbance of organic nature (physical). Inebriety is prone to develop as a frank case at the critical epochs of life, namely, pubescence, adolescence and involution. Developing during involution, it is generally the effort of an individual to maintain his productive power by recourse to artificial stimulation. The frequent inception of inebriety at these periods suggests an analogy to the psychoneurosis. Inebriety, being an expression of neuropathy or psychopathy, may be preceded by or accompanied with a multiform nervous syndrome; thus each case is essentially different.

The heredity element in inebriety is considerable and is undoubtedly a powerful predisposing cause. A history of decided intemperance in the parents existed in over 40 per cent. of Neff's patients, while 15 per cent. gave a history of defective ancestry, insanity, neuropathy, drug addiction or tuberculosis being present on the maternal or paternal side. Approximately, 5 per cent. of the patients showed preexistent mental symptoms which could be differentiated. Some of these were distinct cases of psychasthenia, others were of the milder forms of manic-depressive insanity. Neff feels warranted in corroborating the statement made by others that an inherited neurotic or psychic tendency is present in a considerable number of inebriates. Many of these individuals admit peculiarities during pubescence and adolescence, showing clearly neurotic or psychopathic conditions which have antedated the alcoholic manifestation.

9. **Tuberculous Peritonitis.**—Stone asks that we treat tuberculous peritonitis as respectfully as though one had found tuberculous infiltration in the lung top. The patient is infected with tuberculosis; treat him with the best hygienic surroundings that are possible: above all, rest and restraint at first, and then very gradually increasing exercise. If ascites is present, do not be in a great hurry for it to disappear. It may do so spontaneously. Great distention needs relief, of course, either with the aspirator or the aid of the surgeon. When the turn for the better comes, the patients begin to improve in a most remarkable manner. There is no reason why the patient should be withheld from any legitimate operation that may come up in the course of the disease. The disease is tuberculosis and the prognosis is favorable in the simple, uncomplicated cases of serous involvement. When the lung or other distant organ is also involved, the favorable prognosis rapidly diminishes. But in the true cases of tuberculous peritonitis in which no other focus can be demonstrated, the chances of ultimate arrest under properly conducted hygienic treatment are good. They are not enhanced by surgical intervention without distinct purpose, and any such operation must be treated not as itself curative, but as a step or incident of the "cure."

17 *Malnutrition in Infancy and its Relation to Gastric Digestion. I. J. Tint and L. Breskman, Philadelphia.
18 Infection with *Balantidium Coli.* I. W. Brewer, Samar, P. I.

11. **Suprapubic Prostatectomy.**—In 16 cases, Lilienthal performed the operation of suprapubic prostatectomy in two stages. The average age of these patients was 71, the youngest was 52 years old, and the oldest 77. All except one left the hospital either entirely healed or with a superficial granulating wound. All were well so far as urination was concerned, and all who were questioned concerning sexual ability reported potency, most of them increased potency. In several cases a bacteriuria persisted for weeks or months after the operation, but it disappeared under long-continued hexamethylenamin medication. In this list of 16 cases the longest interval between the 2 stages was 20 days and the shortest was 2 days, average about 8 days. The average period of hospital treatment from the primary operation to the day of discharge was 38 days in the non-malignant cases.

12. Abstracted in THE JOURNAL, May 28, 1910, p. 1811.

17. **Malnutrition in Infancy.**—The examination by Tint and Breskman of the gastric contents of eleven children, mostly under 1 year of age, without vomiting or green stools, showed a constant presence of free hydrochloric acid, rennin and pepsin. Examination of the gastric contents of twenty children under 1 year of age, with green stools, vomiting, and gradual loss of weight, showed an absence of free hydrochloric acid, rennin, and pepsin. In well developed cases of malnutrition, such an absence of gastric activity was constant and persisted throughout the course of the affection.

The authors believe that the stomach very early in life plays an important rôle in digestion through its peptic and rennin activities. Free hydrochloric acid is normally present. With the onset of green stools in artificially fed and breast-fed children, there is an absence of free hydrochloric acid. The absence of gastric activity is relatively constant in children suffering from malnutrition. The milk should be carefully examined for the fat percentage, when such is taken into consideration in making up feedings, particularly in asylums for children.

51. **Hemophilia Neonatorum.**—Under this name, Welch reports a series of cases which includes a number of bleeding babies, in which the etiology of the hemorrhages is unknown. In none of the cases was the hemorrhage due to traumatism. Welch found post mortem that the principal hemorrhage may be either in the brain with extensive laceration, or in the liver, in which case the capsule may be almost entirely dissected from the surface of the organ; hemorrhagic spots in other internal organs and effusions of blood in the various serous

cavities may be found. *In some instances* he found the spinal canal filled with fluid blood.

Case 1: The child was 3 or 4 days old when the bleeding began. Within 24 hours the body was black and blue from subcutaneous hemorrhages; there was a large hematoma occupying one-third of the scalp on one side of the head, and bleeding from the mouth and bowel. The case was thought hopeless. It was at this time Welch made the first injection of normal blood serum; 10 c.c. was administered subcutaneously three times during the first day and once each on the following two days. Within a few hours a decided improvement was noted in the condition of the baby, in that the hemorrhages ceased, the old ones began to fade, and strength returned to the child in a very noticeable way. Within three days the hematoma of the scalp was entirely absorbed, and it was evident that the child was out of danger.

Case 2: On the fifth day blood was found oozing from the vulva. During the sixth and seventh days bleeding was continuous. On the ninth day there was slight oozing from the umbilicus. There was no bleeding after the ninth day. Normal human serum was administered subcutaneously.. This baby left the hospital in due time in a normal condition.

Case 3: The child showed no bleeding until the seventh day. Then a dorsal division of the prepuce was made for phimosis. During the next *four days bleeding recurred about* every 4 hours, often profuse and difficult to control. There was profuse bleeding from the stump of the cord on the seventh day, which continued on the eighth and ninth days, when the stump was invaginated. On the eighth and ninth days there was bleeding from the lips *and gums, and on the tenth day* subcutaneous hemorrhages appeared on the face. Normal human blood serum was injected subcutaneously and the child recovered.

Case 4: On the second day there was slight bleeding from the nose and mouth and small hemorrhagic spots appeared on the arms and back. On the third *day* the hemorrhagic spots increased in size. On the fourth day profuse bleeding from the gums and from the bowels occurred. On the fifth day there was more bleeding from the mouth and rectum and more subcutaneous hemorrhages. On the seventh day more subcutaneous hemorrhages in three places on the body. Subcutaneous injections of normal human blood serum were begun. On the fifty-sixth day the baby died, and autopsy showed the cause to be persistent atelectasis of the lungs involving their posterior half. None of the tissues showed signs of hemorrhage.

Case 5: On the third day blood began oozing from the cord at its junction with the skin, and also from the foreskin, and there was copious bleeding from the nose. The stools were black, showing altered blood. A single injection of 10 c.c. of normal human serum was given, and within 6 hours the bleeding ceased and the stools on the following day were normal.

Case 6: On the second day the child began bleeding from the nose. On the third day it bled from nose and cord, and a large hematoma appeared on the back of the head and neck, extending from ear to ear. On the *fourth day there was bleeding from* the nose and gums and blood was passed in the stools. On the fifth day there was slight bleeding from the nose; one spot was noticed on the right knee and left elbow. Normal human serum was injected. There was no more bleeding after the fifth day and the child was discharged normal 13 days after.

Case 7: Bleeding from the cord and rectum began on the fourth day. On the fifth day bleeding from the vagina and rectum, and two subcutaneous hemorrhages appeared on the left side of the thorax. On the ninth day there was vomiting of blood and slight bleeding from the rectum. On the tenth day there was profuse bleeding from the cord, vomiting of blood, and bleeding from the rectum, two subcutaneous hemorrhages on the right side of the thorax, and others on the elbows and on the back. Normal human blood serum was administered subcutaneously. The child recovered.

Case 8: On the third day the child began bleeding from the mouth and rectum, and under the skin covering the left scapula. On the fifth day bleeding continued; there was no bleeding on the sixth day. On the seventh day there was bleeding from the rectum. *Normal human blood* serum was injected subcutaneously. The child recovered.

Case 9: The child had severe hemorrhage from bowel and stomach, but recovered after serum injection.

52. **Myasthenia Gravis.**—Pemberton found that in myasthenia gravis there may be marked loss of calcium by the tissues even under circumstances of marked nitrogen retention. The creatinin output in myasthenia gravis may be reduced to a point below normal; the output of creatinin nitrogen expressed in percentage of the total urinary nitrogen may be almost as low as that seen in conditions of true muscular wasting. These facts taken together form a reasonable basis for the belief that myasthenia gravis is a disease of deranged muscular metabolism, and that one, at least, of these two factors (that is, the loss of calcium) *may stand in such a causal* relationship as to indicate the therapeutic administration of that element.

56. **Murmurs in Pulmonary Tuberculosis.**—Murmurs over the chest not demonstrably dependent on cardiac or vascular disease, when listened for carefully under favorable circumstances and repeated *examinations*, are *found* frequently in tuberculosis. They were heard by Montgomery in nearly three-fourths of the advanced cases. These murmurs are usually systolic in *time, and faint* in intensity, in Montgomery's cases three-fourths being faint. They are generally soft and whiff-like in character, though they may be rather loud and harsh. In the majority of cases these murmurs are heard repeatedly and usually intermit only temporarily. The areas where they are most commonly heard, and where their maximum intensity most often occurs, are at the base of the heart, chiefly to the left of the median line at the cardiac apex (a little over half as often as at the base), and at the inferior scapular angles posteriorly, more often on the left side. These murmurs are more frequent over the front of the chest than the back; they are more frequent and more widely distributed over the left side in front than the right. They are heard in a relatively small number of cases in the axillæ. They may be very limited in extent or may cover the entire chest. In Montgomery's cases the murmurs were usually heard best *during the quietest* part of the respiratory act, that is, during expiration or the respiratory pause, and during suspended respiration; less often they were limited to the end of inspiration and beginning of expiration, and rarely they were heard during inspiration only. These murmurs are modified at times, by position, more often by excitement and exertion. With the possible exception of the left side in front, murmurs in advanced cases are heard more frequently over normal or hyperfunctionating tissue than diseased tissue, this being particularly noticeable at the bases posteriorly. The etiology of these murmurs is usually obscure, and causes probably responsible in a certain proportion of all cases are hard to establish in individual cases. In about 7 per cent. of the cases with murmurs, mitral regurgitation dependent on weakness of the heart muscles was diagnosticated. For prognosis and treatment little is gained from these murmurs of undetermined origin. Even when they seem to depend on the advance of the tuberculous process they furnish little information unobtainable in other ways.

Out of 171 cases of pulmonary tuberculosis (over one-half being far advanced cases, and nearly three-fourths of the patients being females), a diagnosis of endocarditis was made in 2 cases (mitral regurgitation once, and mitral regurgitation and stenosis once), and a diagnosis of probable endocarditis (mitral regurgitation) was made in a third case. That is, endocarditis was diagnosticated in 2 or 3 of 171 cases. In none of these cases was a diagnosis of disease of the pericardium or of the aorta made. Myocarditis is not infrequently demonstrated microscopically in hearts from persons dying of tuberculosis, and its occurrence is often suggested clinically. The diagnosis, in individual cases of tuberculosis, however, is usually very difficult, first, because of the frequent absence of important signs, for instance, certain types of arrhythmia; and second, because many of the symptoms of myocarditis may also be produced by tuberculosis. Heart disease with failing compensation, Montgomery has never seen in very far-advanced tuberculosis.

68 Adrenalectomy *and* Glycosuria. H. McGuigan, St. Louis.

66. **The Reactions of the Vasomotor Center.**—Sollmann and Pilcher describe a method for studying the reactions of the vasomotor center by which the *complicating* factors of the force of the heart's action and the influence of peripheral vasomotor action can be obviated. The method consists in isolating an organ, the spleen usually, from its connection with the central vascular system, but retaining its vasomotor ner-

vous connections and perfusing it with Locke's fluid. They usually curarized the animals and found that curare alone slightly stimulated the vasomotor center after a temporary fall of pressure due to peripheral action. During the brief vasomotor action of curare, there is a considerable peripheral block to weak and moderate vasomotor impulses. This may be completely overcome by strong vasomotor stimulation (if the quantity of curare is not too large). Maximal stimulation of the central stump of the sciatic nerve stimulates the vasomotor center so as to decrease the spleen-flow by 20 per cent., on an average (the blood pressure rising 30 mm. to 25 per cent.). The result is not affected by previous section of the vagi. The absolute rise of the pressure is the same for blood pressures ranging between 70 and 160 mm. The percentile rise therefor varies inversely to the level of the blood pressure. The response of the vasomotor center does not bear any simple relation to the blood pressure. The response of the vasomotor center to sciatic stimulation is only about one-third as powerful as is its response to asphyxia. The absolute change of the blood pressure appears to be a more correct index of degree of vasomotor response than the percentile change.

67. **Acapnia and Shock.**—Henderson and Scarbrough continue their discussion of the acapnia theory of shock and endeavor to show the importance of an undue loss of carbon dioxid in producing fatal apnea in the course of administration of anesthetics.

> Anesthetics tend to prevent shock because they diminish the rapid breathing due to pain and thus obviate the development of acapnia (absence of carbon dioxid from the blood).
>
> Respiratory excitement during the initial stages of anesthesia diminishes the carbon-dioxid content of the blood and thus tends to induce a subsequent failure of respiration. Similarly ether, unless neutralized by morphin, in dogs often causes hyperpnea, acapnia, and consequently fatal apnea.
>
> Morphin raises the threshold for carbon dioxid more than it does the afferent threshold of the respiratory center. Chloroform elevates the latter threshold more than the fo[illegible] lessens the sensitiveness of the respiratory [illegible] more than it does the sensitiveness to extet [illegible] form produces an opposite effect. Ether in [illegible] found anesthesia exerts a respiratory stimulant influence which lowers the threshold for carbon dioxid and thus tends to induce acapnia.
>
> Apnea in anesthesia depends, in the same manner as to normal life, on the relation of the level of the threshold of the respiratory center for carbon dioxid to the quantity of *carbon dioxid in the* blood and tissues. Whenever the former is above the latter, spontaneous breathing ceases, that is, the less sensitive the respiratory center is and the less carbon dioxid in the blood, the *more likelihood* of a cessation of the breathing.
>
> Under anesthesia the threshold for carbon dioxid (that is the point at which carbon dioxid will excite breathing) may be elevated 60 per cent. above normal, or depressed 50 per cent. below normal. Such a depression of the threshold causes vigorous hyperpnea. If long continued, it results in intense acapnia, that is, the excessive breathing removes the carbon dioxid from the blood.
>
> Chloroform apnea may be regarded as merely a form of apnea vera.
>
> Experiments show that ether-hyperpnea is as effective as pain hyperpnea as a means of inducing a subsequent fatal apnea vera. For instance, administration of ether in such a manner that rapid breathing is occasioned is as likely to induce shock as intense pain.
>
> In normal subjects under chloroform [illegible] ways fails before the heart. Patients wh [illegible] period of sickness and suffering, or their [illegible] are hypersusceptible to the toxic influenc [illegible] cases the circulation fails first, or simultaneously with the respiration.
>
> Hypercapnia during anesthesia may be the factor which determines the development [illegible]
>
> Skillful anesthesia [illegible] the threshold of the respiratory center for [illegible] arly normal level and in avoiding the develo [illegible] a or hypercapnia.

74. Abstracted in THE JOURNAL, May 14, 1910, p. 1630.

75. **Treatment of Eclampsia.**—The desideratum, according to Jacobsen, was to find a substance which mixed with the water to be administered shall be harmless and will not increase the molecular concentration and specific gravity of the blood, which are already too high. It seemed to him that pure water created irritation of the bowel. The usual physiologic saline solution was rejected as dangerous and illogical. If the patient is dying from a retention of salts in the blood it would be worse than folly to administer more salt in solution. After going over the field carefully, Jacobsen decided that a solution of sugar would meet all indications. Sugar was decided on because of its high molecular weight. The weight of a molecule of sugar is stated to be 342, while that of salt is 58. It is clear that many more of the lighter or smaller salt molecules will go into a given volume of water, than the many times heavier or larger sugar molecule. Therefore, the molecular concentration of the blood would be speedily reduced by diluting it with sugar water, whereas it would remain the same or be increased by administering salt solution.

This seemed rational and was done in several cases, two of which are briefly reported. While under the sugar-water instillation treatment, the specific gravity of the patient's blood was observed by Hammerschlag's method and recorded. It was found that remarkable improvement took place in the condition of the patients under the continuous rectal administration of sugar water by the drop method (Murphy) and that the specific gravity of the blood fell to 1052 from 1060. Both patients made a good recovery. In addition to the sugar-water instillation only water was given by mouth for three days and the usual treatment in these cases carried out, namely, veratrum viride hypodermically, patient wrapped in blankets surrounded by hot-water bottles to induce perspiration, catharsis, later salt-free diet. Jacobsen says that it was astonishing to see the large quantities of sugar water that were absorbed by these patients, and how the quantity of urine and perspiration increased, bringing about improvement in the patients' condition from the start.

78. **Mechanism of Third Stage of Labor.**—Harper says that the placenta is commonly delivered as an inverted cone, the fetal surface presenting; the membranes follow, reversed. This may be called the normal mechanism because it occurs in the majority of cases; it may be explained by the action of the uterine forces on the placenta in its common position in the upper uterine segment, and it is attended by expulsion of the membranes more often intact. Uncommonly, the placenta is delivered as a cylinder, the edge or the edge and maternal surface presenting; the membranes follow, their anatomic relations preserved. This may be termed the abnormal mechanism because it occurs in the minority of cases; it may be explained by the action of the uterine forces on the placenta in its uncommon position in or encroaching on the lower uterine segment; and it is attended by the expulsion of the membranes often incomplete and detached to a greater or less degree.

79. **Extrauterine Pregnancy at Full Term.**—The two cases reported by Nutt were tubal pregnancies at full term with very little departure from normal pregnancy in so far as the mothers' symptoms and feelings were concerned. In each case at the end of the gestation period labor pains were experiences which subsided with the death of the child.

80. Abstracted in THE JOURNAL, June 18, 1910, p. 2090.

also to determine whether the bacillus present was of the human or bovine variety, Clarke and Forsythe have been using this method for about 18 months, and now record the results in 250 consecutive cases. The technic is simple. A 25 per cent. solution of old tuberculin is made up with a diluent consisting of 1 part of 1 in 20 phenol-glycerin and 2 parts of normal saline solution. The solutions are kept in 3 pipette stoppered bottles containing, respectively, the diluent for control, bovine and human tuberculin.

On the right forearm is placed a drop of the diluent, and at some distance a drop of human tuberculin, and the skin is scarified through each drop with a straight Hagedorn needle. The left arm is similarly treated with bovine tuberculin. A different needle, which is kept in alcohol, is used for each solution.

If a reaction occur, a small red papule appears in 24 hours, increases in size for three or four days, and then gradually fades in about a week, leaving in some cases a slight desquamation or pigmentation. In a few cases the papule becomes vesicular, and in still fewer the reaction is delayed until the fifth or sixth day. The control should show no reaction on the third day. In every one of the first 250, there was some reason to suspect the presence of tuberculosis. Seventy-nine cases were certainly tuberculous, in 42 the diagnosis of tuberculosis was highly probable, and in 129 there was no evidence of tuberculosis other than the reaction when present.

All cases certainly tuberculous gave one or both reactions, with one exception, namely, a case of tuberculous meningitis in which tubercle bacilli were found in the cerebrospinal fluid. This patient died. Of cases probably tuberculous, one or both reactions were present more frequently where the probability was greater than where the probability was less. In cases suspected of tuberculosis, where there were no definite diagnostic signs, one or both reactions were present, more frequently after the age of 15 years and most frequently in patients over 45 years of age. It is obvious, however, that the probability of any individual being tuberculous increases with his age. In the pulmonary cases, of those certainly tuberculous, 2 gave a bovine reaction, and 22 gave both reactions. Of those almost certainly tuberculous, 2 gave a human reaction, 1 a bovine, and 39 gave both reactions. In these two groups of 66 patients examined, 61 gave both reactions, which in 28 cases were equal, in 17, the human, in 16 the bovine being the greater; 2 gave the human reaction only, and 3 the bovine. In all cases some reaction occurred.

24. **Constipation in Childhood.**—To combat constipation in infancy, Poynton says it may be quite sufficient to use manna, which should be dissolved in hot water and strained through muslin. This remedy, no doubt, often fails, but it is very satisfactory when effectual, and for this reason worthy of trial. Some light massage along the colon will help these cases. Salines are most valuable remedies. The secret of the successful use of salines lies in their regular employment, in sufficient dosage to produce a thorough relief of the bowels. The initial dose must be an experiment, but, once ascertained, it should be persisted with until a regular habit had been established and then should be diminished cautiously. If too little is given, griping pains and distention may result, and if too much, the motions will become unduly frequent and liquid.

A likely prescription for a child 2 years of age would be:

℞	gm. or cc.		
Magnesii carbonatis		66	gr. x
Sp. chloroformi		13	mii
Syrupi	1		mxv
Aquæ	8		℥ij

To be taken twice a day—after meals.

It would be necessary, if there has been constipation of some standing, to give a dose of calomel or grey powder before commencing the saline treatment. Castor oil is well known as a very safe aperient, but has the disadvantage of intensifying the constipation if used in occasional doses. In spite of this it is invaluable when it is necessary to clear away curds in milk dyspepsia, and it can then be followed by mild salines. If a small and delicate infant has to be treated, the castor oil can be given with an equal part of pure olive oil. Castor oil has another useful function in young children, when there is irregularity of action of the bowels. In this particular class of case there is at one time constipation, at another diarrhea. Small doses of this drug given once, twice or thrice a day will often correct either of these irregularities. Five minims given in a mixture with a carminative twice a day is an average dose for a child of 12 months.

When the constipation is associated with deficient hepatic action, indicated by pallor of the stools, grey powder is a useful remedy, and this may be combined with powdered rhubarb as follows:

	gm. or cc.	
Pulv. hydrargyri cum creta.	06	gr. i.
Pulv. cinnamoni	03	gr. ss.
Pulv. rhei	2	gr. iii.

Fiat pulv.
To be given at night.

Poynton has used phenolphthalein in a considerable number of cases of constipation in mentally deficient infants and children, and he has found it sometimes very convenient and efficacious in these cases in doses from ¾ of a grain to 2 grains.

25. **Constipation in Infants.**—The more important of the many causes of constipation are classified by Pritchard as follows:

A. ORGANIC IMPEDIMENTS TO PERISTALSIS:
  (1) Congenital malformations:
    (a) Atresia recti,
    (b) Imperforate anus,
    (c) Dilated colon (Hirschsprung's disease).
  (2) Acquired structural alterations:
    (a) Dilated, convoluted, or lengthened colon from overfeeding, or flatulent distention;

(b) Inflammatory conditions of (i) peritoneum (peritonitis); (ii) bowel wall (results of long standing colitis or dysenteric diarrhea): (iii) mucous membrane (inspissated mucus in chronic colitis).

B. INTERFERENCE WITH NERVOUS MECHANISM OF PERISTALSIS AND DEFECATION:

(1) Organic (meningitis, hydrocephalus, tumors of brain and spinal cord);
(2) Toxic conditions:
  (a) specific infections (fevers, etc.);
  (b) specific poisoning due to drugs (opium, lead, excess of lime water, etc.);
  (c) intestinal toxemias due to decomposition of food in the bowel.
(3) Exhaustion of nerve-centers due to over-stimulation by:
  (a) diarrheas;
  (b) purgative drugs.
(4) Interference with the peripheral nervous mechanism by:
  (a) Hypersensitiveness of anal sphincter (fissure of anus),
  (b) Anesthesia of sensitive zone of rectum (by enemata suppositories, presence of foreign bodies, etc.).

C. FAULTS IN THE INTESTINAL CONTENTS:

(1) Insufficient food (starvation, vomiting),
(2) Deficiency of fluid (dehydration of tissues by fevers, loss of blood, want of bile and intestinal secretions).

The treatment of constipation in infants is summarized by Pritchard as follows:

(1) In all cases the exciting cause, such as deficiency or excess of food, or qualitative faults, must be treated by appropriate means; (2) the motions may be softened by—(a) free doses of petroleum emulsion, and (b) in aggravated cases by small doses of drugs which promote intestinal secretion and the outflow of bile; (3) inertia of the bowel may be treated by—(a) massage, or massage combined with electricity, and (b) in aggravated cases by cascara sagrada and nux vomica; (4) in cases in which a chronic colitis complicates the condition, a preliminary course of irrigation (Plombières method) may be employed; (5) in cases in which the motions are light colored and offensive, liquor pancreaticus may be added to the petroleum; (6) in all cases regularity of habit must be enforced by careful and systematic training.

27. **Habitual Constipation.**—It can often be found out from a patient, says Russell, that certain exercises, some simple dietetic measure, or the drinking of water the last thing at night or first thing in the morning, are sufficient to cause bowel action; whenever this is the case these measures ought to be persevered with. Bowel action is favored in many persons by regularity of practical suggestion. The smell of castor oil is said to be sufficient for some. Minute doses of common aperients are ample for others, so minute in fact, that some people insist that the action is by suggestion. Whatever it be, the remedy that acts so is the ideal one for the individual. If a laxative drug has to be taken regularly, perhaps daily, the drug which in smallest quantity ensures movement is the ideal one for the individual, and can often only be found by experience.

31. **Agar-agar Treatment of Constipation.**—The constant or daily use of agar-agar, according to Gompertz, brings about normal evacuations. It is a helpful and harmless remedy that may be used indefinitely without the diminishing and aggravating effects of drug-treatment. The fact that it produces a condition which approximates natural functions, affording necessary relief without interfering with other medical treatment, should entitle agar-agar to professional consideration, and overthrow any objection against its use.

32. **Sour Milk in Constipation.**—Luke outlines his practice as follows: Patients usually take their first glass at breakfast in the place of porridge. It is convenient to turn the glass out into a cold pudding plate and sprinkle the curd with sugar, or with a mixture of cinnamon—powdered—with sugar. Some patients enjoy the slightly acid, sharp taste, and find it more agreeable and appetizing without any added sugar. A brown meal biscuit goes well with it. At lunch the patient takes the curd instead of soup, and at dinner to replace any sweet pudding or pastry by the curd. This makes a convenient distribution and prevents the patient feeling that the extra bulk of food is embarrassing.

Some patients, who are on a purin-free diet and do not take afternoon tea, find a glass of curd nice at 4 p. m., especially in hot summer weather. Luke has never found patients to suffer any material inconvenience or digestive discomfort which was traceable to this diet. If any flatulence or discomfort is experienced for a day or two, the amount of milk taken should be reduced and gradually increased once more as the patient gets accustomed to it. The time for which the milk is taken should be never less than six weeks, if it agrees at all, and it may be quite well continued for six months, and afterward taken occasionally as an article of daily diet.

43 *After-results of Abdominal Operations on the Pelvic Organs in 1,000 Consecutive Operations. A. F. Giles.
44 *Menstruation in Europeans, Eurasians and East Indians in India. J. C. H. Leicester.

43. **After-results of Abdominal Operations.**—As the result of his study, Giles claims that the general health after myomectomy is very good, 85 per cent. of patients being in quite good health, or at least better than before the operation. The likelihood of recurrence of fibroids is relatively small, the cases of recurrence amounting to under 10 per cent.; 90 per cent. were free from recurrence after periods varying from 1 to 7 years. The menstrual loss is moderate or scanty in about 85 per cent. of cases, many of the patients stating that the loss was less than before the operation. The uterus from which fibroids have been removed may be serviceable for child-bearing, 3 out of 15 married women under 45 having become pregnant subsequent to the operation; the uterus bears the strain of pregnancy and labor without difficulty.

44. **Menstruation in Europeans, Eurasians and East Indians.**—Leicester found on investigation that menstruation begins at a later period among the Europeans than among those of mixed extraction; and that, furthermore, the more the dark element predominates the earlier is the age of onset. Among the East Indians, 53.73 per cent. begin to menstruate before the age of 14 years; of Eurasians, 48.22 per cent.; and of Europeans 39.37 per cent.; while in this latter class of those who had been borne and bred in India, 39.81 per cent. commenced to menstruate before the age of 14, and 38.98 per cent. of those who had not been borne in India. This would seem to show that the onset is slightly earlier among those Europeans who are born and bred in this country than among those who come out here at a later age; but the difference is so slight that in the absence of further figures no stress can be laid on this point.

The average age of commencement works out at 14.32 years in Europeans, 14.15 years in Eurasians, and 13.86 years in East Indians. From these figures it would appear that the age of commencement of menstruation among Europeans in the Tropics is perhaps slightly earlier than it is in temperate climates, this point being somewhat more marked among those who have been born and bred in India; the difference is, however, so slight that it certainly seems as if the effect of climate had been unduly exaggerated by certain writers, the question of race apparently being of far more importance in this matter.

The average periodicity of the flow appears to be more regular in Europeans than in those races of mixed extraction. The average duration of the period is probably practically the same in all these races with the possible exception that it is of slightly shorter duration in Europeans coming to India than in those of other classes. The commonest type of menstrual pain among all classes seems to be that occurring during the period only, and the least common that occurring only before the onset of the flow. The effect of the Indian climate on the periods of Europeans coming out to the country for the first time after the establishment of menstruation is nil in nearly two-thirds of the cases, and in less than one-third is there any increase in the amount lost. The effect of climate, both as to the onset of menstruation and also as to the amount lost at the periods, has probably been overestimated. Race would seem to have far greater influence on onset than climate.

57 Children's Plays. (Les jeux des enfants. De leur influence en hygiène.) Delobel.

51. Epidural Injections in Treatment of Incontinence of Urine.—Sisto says that the epidural space is a favorable route for absorption of a drug on account of the abundance of veins in the region, permitting much more rapid and extensive absorption than by the subcutaneous or gastric route. It is the ideal method, he declares, for anesthetizing the spinal roots while it is free from the dangers of the lumbar injection into the subarachnoid space and from the inconveniences and perils of intravenous injections. He reports a case in which injection of less than 5 c.c. of physiologic salt solution at blood temperature cured completely life-long nocturnal incontinence in a girl of 14, otherwise healthy. There has been no recurrence during the more than two years since. He followed Cathelin's directions in every point, and commends the epidural injection, after failure of all other measures, citing Zubizarreta's favorable experience with 12 cases. The latter noticed a neuropathic tendency in all his patients and states that the epidural injection in one case was made in the ward where there were four others. The child screamed while the injection was being made, and none of the children was incontinent thereafter for several nights. Bordot has recently reported that he cured 5 out of 11 children with incontinence by the epidural injections, and Sisto has not found the method invariably effectual.

56. Tuberculous Peritonitis without Ascites.—In the case reported a 2-year-old boy developed symptoms suggesting recurring acute appendicitis, except that McBurney's point was not tender, and the child was kept on a light vegetable diet for a few months. An attack of pain in the kidney region at one time was assumed at first to be due to nephritis, but the urine persisted comparatively normal. The recurring abdominal pain at last compelled a laparotomy, when the appendix was found sound but the peritoneum proved to be studded with tubercles without any tendency to ascites. The child was sent at once to a sea-shore sanatorium and now, a few months later, seems to have entirely recovered. Delille comments on the case that months were wasted with the light vegetable diet when the child should have been given general treatment for the tuberculosis; the tuberculin skin reaction would probably have cleared up the diagnosis, but no one thought of this as there was absolutely nothing in the family or environment to suggest possible tuberculosis.

Archives Générales de Chirurgie, Paris

58 *Tuberculosis of the Adnexa. (Tuberculose des annexes de l'utérus.) A. Rives.
59 Multiple Fracture of the Arm. (Fractures simultanées du radius et du massif épicondylien de l'humérus avec luxation du coude en arrière.) Vandenbossche.

58. Tuberculosis of the Adnexa.—Rives has compiled 250 cases of a tuberculous process in the adnexa, published in the last decade. Although the years between 15 and 25 are most affected yet the list of cases includes all ages from infancy to old age. A predisposition is evidently afforded by congenital deformities, stunted development and neoplasms, especially ovarian cysts, and gonorrheal lesions, fully one-tenth of the cases occurring in virgins. Treatment should be the general measures for tuberculosis, and severe lesions may retrogress under this alone. Surgical measures are indicated only in case of vital indications and a primary focus or to remove absolutely useless organs. In a number of cases on record the lesions subsided and menstruation and conception followed. Operative treatment does not seem to give permanent cures; a survival of more than a year is recorded in only 38 out of 275 cases in which it was attempted. The number of survivals after minor, conservative operations is as large as after more radical measures. The rarity of a primary localization also tends to discredit the latter. The summaries of 12 cases from the Montpellier hospitals are appended. Three patients are in good health to date, from 4- to 7 years after abdominal or vaginal panhysterectomy; in the other cases the operation is comparatively recent. Differentiation is generally difficult.

Archives des Maladies de l'App. Digestif, Paris

April, IV, No. 4, pp. 177-240

60 *Foreign Bodies in the Esophagus. (Corps étrangers de l'oesophage.) G. Guisez.
61 *Digestive Disturbances and Intercostal Neuralgia. M. Loeper.
62 **Normal Toxicity of the Food. G. Linossier and G. H. Lemoine.*

60. Foreign Bodies in the Esophagus.—Guisez tabulates the details of 49 cases from his experience and discusses them from the standpoints of esophagoscopy, clinical observation and treatment. The mucosa tolerates bodies with round edges, such as a coin; only slight superficial lesions of the mucosa were evident in any such cases even when the foreign bodies had been impacted for several days up to four years. The foreign body was a chunk of meat in one case and in some others bismuth, taken for Roentgen ray examination, had packed into a lump from spasm of the cardia or cancerous obstruction.

61. Digestive Disturbances and Intercostal Neuralgia.—Loeper has encountered a number of cases in which gastric dyspepsia, pain and oppression in the stomach and retarded evacuation followed typical intercostal neuralgia with or without zona and zones of hyperesthesia, the digestive disturbances developing only after the neuralgia, of which they were thus evidently a complication, a visceral manifestation of a superficial neuralgia, which, as the patients said, "settled in the stomach." In some similar cases on record the visceral manifestations were more in the intestines. Diarrhea followed zona in Rouyer's case. The data to date seem to indicate, Loeper thinks, that the primary trouble is in the spinal roots, and the relief from lumbar puncture in some cases seems to sustain this view. Otherwise treatment is only that for neuralgia in general; with a suspicion of syphilis, specific treatment may give brilliant results as in one of the cases reported.

62. Normal Toxicity of the Food.—Subcutaneous injection into animals of various albuminoid substances of animal origin showed that all had a decided and constant toxic action, unless they had been previously treated with gastric juice; this seemed to annul their toxicity completely. Heating the substances beforehand also annulled their toxicity for the kidneys. It is evident, Linossier and Lemoine remark, that the least irregularity in the natural defences in the gastrointestinal tract leaves the toxicity unannulled. They add that life is an uninterrupted struggle, inevitably terminating in defeat, and it is curious to learn that included among the enemies which the organism has to contend with are meat and milk, supposed to be its most potent allies. Digestion is the battle, and the conquerors make slaves of the conquered. But years of this struggle finally wear out the organism even if it has been constantly victorious.

67 Localized Black Sweat; Melanephidrosis. (Nouveaux faits concernant la chromidrose.) R. Blanchard.

65. **Primary Tumor of the Liver.**—Rénon and his coworkers explain primary hepatoma as an aberrant embryonal tumor resulting from the revivification of the normal embryonal process later in life.

66. **Serodiagnosis of Actinomycosis.**—Widal was able to differentiate actinomycosis by the seroreaction in 8 cases, the only negative reaction being in a case in which the cure had been complete for over four years. The specific reaction is both by agglutination and by fixation of complement by means of the spores of the sporotrichum. Actinomyces cultures can not be used for the tests, but the generic reaction with sporothrix spores is constant and lively. It is specific for actinomycosis, sporotrichosis and thrush, but these can be readily distinguished. Sporotrichum cultures can be preserved indefinitely, he says, by sterilizing with formalin.

75 *Tabes and the Puerperium. (Tabes et puerpéralité.) Gaussel-Ziegelmann.

72. **The Limit of Assimilation of Sugar in Uncontrollable Vomiting of Pregnancy.**—Lequeux calls attention to the important information to be derived from digestive *glycosuria e saccharo* for estimation of the gravity of the condition in uncontrollable vomiting of pregnancy. Pinard has recently declared that the pulse is the infallible index of the condition, regarding a pulse of over 100 as an indication for immediate interruption of the pregnancy. But he has encountered one case at least with fatal coma with a pulse *not over 80*, and Lequeux here reports three cases in which *the pulse was never high* although the condition was extremely serious. He tested the power of assimilation for sugar and found that it was materially lowered in these severe cases; it paralleled the general condition so closely that he is convinced that the glycolytic power is the most reliable index of the condition of the liver and hence of the approach of danger. He gives the patients from 20 to 50 gm. of cane sugar and his experience has shown that when the power of assimilation is below 1 gm. per kilogram of body weight, the prognosis is very grave and the pregnancy should be terminated at once. The lower glycolytic power may persist for some time, indicating that the woman should be regarded as having pronounced liver trouble and should be treated accordingly until conditions return to normal.

75. **Tabes and Pregnancy.**—The history of tabes in connection with childbirth shows that the chances are all in favor of the delivery and puerperium being normal. The mother does not seem to incur any special danger from the coexistence of the tabes, and the children are viable and healthy in a large proportion of the cases. In a series of 68 cases on record of pregnancy in the course of tabes, two-thirds of the 27 children were living at last accounts and one-third of the 41 children of mothers whose tabes developed after the onset of the pregnancy. *The tabes itself does not seem to affect the children;* the relatively high mortality is due to the preexisting syphilis. Delivery is liable to be exceptionally brief on account of the lack of tone in the muscles, but otherwise the obstetrician should deal with the tabetic as with the healthy parturient. If the syphilis is of recent date or there is a history of preceding abortions, mercurial treatment during pregnancy is indicated on behalf of the child.

79. **Gases in Treatment of Gastric Disturbances.**—Hulmann has been studying the gases generated in the stomach in the course of digestion, for which he has devised a simple apparatus, using a branching Faucher tube. In treatment of pathologic conditions he utilized the information thus derived, injecting a mixture of air and carbon dioxid in two patients with acid dyspepsia, air and oxygen in a patient with glandular atony, pure nitrogen in a case of nervous atony and pure oxygen in a case of dilatation of the stomach and autointoxication. The results he regards as encouraging, and he is now experimenting to learn whether injection of some gas before meals may not be able to stimulate the gastric secretions and promote digestion. Mere evacuation of the gases generated in the stomach gave great relief in three other cases.

84 *Estimation of Gastric Acidity by Effervescence on Ingestion of an Alkali. (Une nouvelle méthode d'examen fonctionnel de l'estomac.) E. Fuld.

84. **Estimation of Gastric Acidity by Effervescence on Ingestion of an Alkali.**—Fuld has the patient drink a solution of sodium bicarbonate and then applies the stethoscope to the stomach and estimates the amount of hydrochloric acid present by ausculting the effervescence that follows the contact of the alkali with the acid medium of the stomach content. When the formation of bubbles can no longer be heard, percussion will reveal the amount of gas generated and radioscopy will confirm the degree of distention of the stomach. The acid naturally in the stomach takes the place of the tartaric acid

used for the usual effervescence inflation test. He declares that when it is impossible to withdraw the stomach content for direct inspection, this sodium bicarbonate test is superior to all other measures on account of its simplicity, ease and precision, this intragastric acidimetry by saturation, corresponding to titrametry in chemistry, permitting the determination of the total amount of free acid in the stomach at a given moment. The degree of concentration is expressed by the rapidity with which the phenomena of crepitation occur. He adds that if in the normal stomach one hour after a test meal the stomach content may be assumed to average 250 c.c. with a free acidity of 30, the neutralizing dose of sodium bicarbonate would be 0.63 gm. and the carbon dioxid generated would amount to 0.33 gm. which would fill a space of 187 c.c. After cessation of the effervescence following ingestion of this dose, if a new dose is ingested and effervescence follows anew, this shows, he says, that there is an excess of acid present. In conclusion he remarks that the special value of this test may prove to be in revealing anachlorhydria, pointing to gastric cancer.

87. Treatment of Scarlet Fever.—Although the streptococcus is not regarded as the causal agent of scarlet fever, yet its cooperation is what seems to make the disease so murderous, according to the opinion of Jochmann and Michaelis. They have obtained good results in treatment by combining antistreptococcus serum with vaccine therapy; neither alone gave such good results. The method was applied only in the severer cases; that is, in 52 out of 400; 14 of the patients died and 38 recovered, all without complications of any kind. The absence of nephritis they regard as more than a mere coincidence. In their previous experience scarcely any of the patients recovered from whose blood during life streptococci could be cultivated, but among those who recovered under the combined treatment there were a number in this category.

93. Treatment of Pericarditis.—Ortner emphasizes the importance of a history of syphilis or rheumatism as a guide to treatment; the salicylates rarely prove effectual in rheumatic pericarditis but they should always be given a trial. He remarks that pericarditis may occur in an encapsulated form; there may even be multiple encapsulated foci; some serous, others with purulent contents. Absolute repose should be continued until the last trace of effusion and of friction sounds has vanished and the heart action is entirely normal. In case of local disturbances he applies cold in the form of an ice bag suspended over the heart, or heat from hot compresses; the latter aid in relieving pain while they have an unmistakable curative action and strengthen the heart. Dry cupping may also prove useful; morphin, he continues, should be given without hesitation in case of excessive pain and restlessness. When there is a concomitant pleural effusion he taps the latter first as this may make it unnecessary to tap the pericardium. The latter measure, however, may render important service even with a purely hemorrhagic pericardial effusion; in two recent cases of hemorrhagic effusion with pericarditis, accompanying scorbutus, the puncture proved a life-saving measure. It should be made only in the side regions of the pericardium.

94. Puncture of the Brain.—Pollack comments on the diagnostic and therapeutic importance of puncture of the brain, not only for acquired hydrocephalus but for cysts and effusions in the meninges or brain, dural hematomas and abscesses in the brain. In a number of cases reported in detail of hydrocephalus, circumscribed meningeal effusions, uncomplicated cysts and dural hematomas the result was a definite cure. The best technic is puncture of the scalp, a small hole bored in the skull with a fine blunt smooth drill and introduction of a fine hollow needle attached to a Pravaz syringe. Larger sized instruments are liable to injure vessels which the fine ones push to one side. Among the instructive cases described in detail is one of an assumed abscess in the brain of a girl of 17; puncture of the right frontal lobe gave issue to 18 c.c. of fluid and a little normal brain tissue, after which the intense headache subsided. A week later the left cerebellum was punctured and fluid spurted, about 60 c.c. being evacuated this time, followed by entire recovery. Neither in this nor in some similar cases were there any pathologic findings in the fundus of the eye or other signs of hydrocephalus. Acute or subacute hydrocephalus in adults is frequently diagnosed as migraine, and a rapidly fatal termination may be averted by prompt puncture, as also in cases of a superficial local intracranial collection of fluid. He adds that especially in the diagnosis and treatment of extradural and intradural hematomas puncture has rendered most valuable service. In some of these cases the limpid fluid found showed that the bleeding had entirely stopped, and the patients recovered at once after escape of the fluid. The most instructive sign in such cases is the violent circumscribed pain experienced at the site of the old trauma when the region is struck; the puncture shows that the trouble is a serous effusion at the site of the injury. In the last case described a young man of a hysteric-neuropathic temperament had a frontal sinusitis after scarlet fever, which healed on evacuation of the focus. Symptoms developed later suggesting possible hysteria or an intracranial process, the former being finally accepted. Puncture however brought pus.

96. Diabetes Mellitus.—Lenné declares that the diet should be individualized for the patient and the special phase of the disease more than is generally done. It has been his experience that the way in which the carbohydrates are prepared for the table is of the greatest importance for their tolerance by the diabetic. They are tolerated best in the form which takes the longest time for their absorption and which passes most slowly into the blood, such as coarse, tough, moist bread rather than fine, dry and toasted bread, Saratoga potatoes instead of soft mashed potato, etc. The behavior of the albumin metabolism is the criterion of the severity of the case and of the permanence of recovery. It is possible, he says, to conceive of a functional diabetes in which the centers regulating carbohydrate metabolism do not functionate normally because the internal secretions of the organs involved do not reach them physiologically, owing to lack of development of the organs or to toxic influences or other causes. As the young organism grows into harmonious physiologic proportions, things right themselves. This assumption would explain Hürter's case of apparently complete recovery from severe diabetes in a girl of 10. Lenné also reports a case of apparently complete cure of a young man of 20 who two years ago presented severe acetonuria and other symptoms of grave diabetes, so that the prognosis was regarded as distinctly unfavorable. What no medical measures had been able to accomplish was realized naturally, probably, by the further development of the organs or centers or both involved.

106 Modern Treatment of Gastrointestinal Disease. (Die moderne Therapie der Magen-Darmkrankheiten.) I. Lipowski. Commenced in No. 18.

105. Tuberculosis in relation to Chlorosis.—Zickgraf makes a practice of applying the tuberculin test in every case of persisting chlorosis, and states that a positive response was obtained in 74.8 per cent. of 55 cases in which there was nothing otherwise to suggest the existence of tuberculosis. This finding confirms his assumption that tuberculosis is responsible for the chlorosis in a surprisingly large number of cases. The reaction was obtained with 5 mg. or less in all but 5 of the patients. In 48 other cases the chlorosis accompanied manifest signs of tuberculosis. In the tuberculous cases in which the chlorosis was the first or one of the first manifestations of the infection, the patients reacted to the tuberculin test with smaller dosage and in a larger percentage than the rest of the tuberculosis suspects, and the percentage of negative responses was less. Sanatorium treatment was indicated for only 56.9 per cent. of the whole number of suspects while it was indicated for 70.7 per cent. of the whole number of chlorotics with or without suspicion of existing tuberculous infection. The general practitioner, he remarks, should examine the lungs with particular care in every case of chlorosis, and if the chlorosis proves refractory to the usual measures he should not hesitate to apply the tuberculin test as tuberculosis may be lurking beneath.

107. Sugar-Poor Mixture for Infant Feeding.—Finkelstein is convinced that serious disturbances are kept up in sick infants by the fermentation and acids generated by even small amounts of milk sugar in the food. When the food is given entirely free from sugar, "fat diarrhea" stops at once, showing that the latter is not primary. Measures to prevent and cure dyspeptic fermentations should include reduction of the amount of sugar in the food and dilution of the salts, with increased proportions of casein and fat, and, as the child improves, larger amounts of easily assimilable carbohydrates. These requirements he meets with a food made by coagulating a liter of whole milk with a little liquid rennet, keeping the milk for 30 minutes at a temperature of 42 C. in the water bath, and then pouring the whole into a linen bag hung up to drip for an hour. The clotted casein is then stirred into a half liter of water and the whole worked through a hair sieve twice at least. The mixture then looks like milk; a half liter of buttermilk is then stirred into it. Buttermilk answers the purpose on account of the small content in milk sugar, the stimulating action of the lactic acid and the comparative durability of the mixture thus prepared. He calls it *Eiweissmilch*, albumin milk, and states that it contains 3 per cent. albumin; 2.5 per cent. fat; 1.5 per cent. sugar and 0.5 per cent. ash: the proportion of ash is thus higher than in ordinary cow's milk, the artificial clotting increasing the amount naturally retained in the clot. The benefit from this food is emphasized as observed in various gastrointestinal disorders, the groups being classified and analyzed in turn. The article is continued.

118 Tuberculin Treatment of Chronic Tuberculosis in the Rabbit. (Behandlung der chronischen Tuberkulose des Kaninchens mit Alttuberkulin.) R. Stumpf.

112. Eclampsia.—Bauereisen reviews the various theories that have been advanced to explain eclampsia, all sustaining the assumption that the disease is the result of an intoxication from disturbances of the metabolism in consequence of the pregnancy. He advises frequent examination of the urine and regulation of the diet if kidney troubles threaten, with considerable reliance on vegetable alkalies. After the onset, delivery can be hastened and the poison got rid of by venesection, promotion of kidney and skin functioning and intake of alkaline fluids. Narcotics should be avoided, he says, as they reduce the oxidizing power of the cells and do direct harm to vital organs. If all these measures fail, decapsulation of the kidney is in order. Experience to date has shown that treatment along these lines is successful and the results are better, the earlier it is instituted. The exact nature of the toxin may be still a mystery, but the struggle against the disease is no longer hopeless.

113. Transplantation of Glands.—Danielsen and Landois conclude this long study of what has been accomplished to date in transplanting glandular organs by stating that the results are very meager in comparison to the expectations and the labor expended. Experience has shown that the results are poorer the more highly organized the tissue transplanted. This applies especially to brain and spinal cord tissue and to the suprarenals. In contrast to these are the good results with purely epithelial glands like the mamma, ovaries, thyroid and parathyroids. The transplantation of ovaries and parathyroids has given especially fine results, but each advance in these lines opens up new problems for solution. Further research is urgently needed, they remark, on the functioning of the thymus, the hypophysis and the suprarenals.

115. Salt-poor Diet.—Leva recapitulates the findings of his recent research on the salt content of various foods, based on 360 analyses. He then discusses the menus that can be made up from the foods containing naturally only small amounts of salt, declaring that custom is responsible for our eating so much salt, and that no harm results from abstention; many primitive races take no salt at all. Meat is the one article that seems to require more salt to render it palatable, especially beef, veal and pork, soups and meat extracts. The bread should be made without salt and vegetables avoided that contain a large proportion, such as celery, spinach and cauliflower. But other vegetables, cereals, beverages, unsalted butter and cream, eggs, etc., form a liberal diet. Canned goods should be excluded as they usually contain a considerable amount of salt, as also mineral table waters. He adds that horseradish, mixed pickles or mustard can disguise the lack of salt.

117. Douche-Massage in Brain and Spinal Cord Disease.—Schuster has the massage applied with one hand while the other plays the douche on the patient. This method of applying the Aachen thermal waters has been found to be especially useful in chronic myelitis, tabes and cerebral syphilis, spinal and progressive paralysis as well as in rheumatism and neurasthenia. With two exceptions all the patients were benefited.

154 Action of Exlusive Meat Diet, Especially on the Thyroid. (Om virkningen af ensidig kjødernæring, særlig paa glandula thyreoidea.) A. Tanberg.
155 Circular Suture of Brachial Artery. H. Wille.

153. **Action of the Electric Current on the Human Body.**—Harbitz discusses 18 cases from his own experience and the factors which determine the outcome. Experience has shown a remarkable difference in the resistance of different individuals to the same current. A workman was killed instantly with a current of 2 amperes and 220 volts, but some others recovered after from 5,000 to 16,000 volts. In one a current of 7,000 volts apparently passed through the head and spine and after unconsciousness for two hours there was acute mania for three hours which then subsided suddenly and completely with no lesions of consequence. In another case a man of 43 came in contact with a current of 30 amperes and 12,000 volts. After a few minutes of unconsciousness, he was able to get up alone, but his right arm was helpless for a time and there were burns on both arms and one leg, and occasional slight pains in the legs for a few months. In another case the head came in contact with a current of 16,000 volts and was much burned and cataract developed later. It is possible that in this case the current did not pass through but merely skipped, with production of a spark, the latter doing the damage. The resistance offered by the skin is great, especially in the palm or sole of the foot, while thin, delicate skin has less resisting power and mucous membranes still less. The resistance is less also if the skin is moist, especially with sweat, or from damp shoes and stockings. Predisposition is of importance. Young people of the lymphatic temperament seem to be especially liable to sudden death in electric accidents; next in order come hard drinkers and persons with heart disease; in one of his cases the electric accident seems to have aggravated an already existing vascular affection. Different species of animals show great difference in their susceptibility, the horse succumbing to a weak current, 400 or 500 volts, while a rabbit may survive the passage of 1,000 volts and the frog 10,000. The autopsy findings in Harbitz's cases are reported in detail. An electric accident is especially dangerous when the chest and heart are involved but the head seems to be less susceptible. Some advise venesection in cases of cyanosis, others advise against it on account of the danger of lowering the blood pressure. Jellinek has recommended lumbar puncture. Massage or regular elastic pressure on the heart may arouse it to spontaneous contraction, supplemented by stimulants and revulsion. These measures for resuscitation should not be abandoned for several hours. Prévost revived dogs by massage of the heart after two hours of apparent death. Schumacher advises in the most desperate cases tracheotomy and massage of the heart for two hours, supplemented, as a last resort, by sending a current of not less than 240 volts through the body, one electrode in the rectum, the other in a moist compress on the heart, applying the current for two or three seconds at a time. It is important to have the patients examined by an ophthalmologist later for detachment of the retina, atrophy of the optic nerve, etc. Tardy eye symptoms were observed by Jellinek in about one-half of his 122 cases of electric accidents (exclusive of 12 fatal cases).

RADIUM'S CONTRIBUTION TO SURGERY*

ROBERT ABBE, M.D.
Surgeon to St. Luke's Hospital
NEW YORK

I have long felt that the study of so novel and extraordinary an agent as radium should not be left exclusively to the student of physics or to the dermatologist, but that it be given a chance to demonstrate the virtues residing in it, if any there be, in the field of general surgery.

During the seven years past, in which it has been possible to obtain the material, I have taken many occasions to give trial to it, and while knowing my endeavors to demonstrate its utility are far from complete, this much can be said, that without prejudice I have applied it in 500 cases of disease, from the large field of exclusive surgical work and have found enough of interest in its application to warrant my speaking of it in the brief time allotted to me here.

From the first I have entertained the attitude of extreme scepticism, and can truly claim that with a wide and lifelong surgical experience my prejudices have been in favor of first resorting to all other surgical measures endorsed by time in cases in which I might desire to use radium. At the expenditure of much time, personal discomfort and expense, keeping an open mind, as it were, my one desire has been, not to exploit radium, but to test it.

A SURGICAL CURIOSITY

The absence of extensive records of its use in surgical literature is amply accounted for by the almost insuperable difficulty in obtaining a sufficient amount for study, and by the great cost of its production. It will be long before these conditions change materially, and it must to some extent remain a surgical curiosity. Yet, if its utility can be demonstrated in any definite way, its production and distribution will surely follow the law of supply and demand.

The world was hardly ceased to marvel at the ultra-scientific, almost inspired, research of Madame Curie, which rent the darkness and laid bare the unsuspected force of radiant energy in matter exhibited in the most demonstrable form of radium. As yet we know as little of it, as of the vital force that actuates our bodies, our functions, our intellects. The needs of surgery are greater than we are willing to admit. The ever-ready scalpel, caustic, cautery, medicine, are still our weapons.

For the moment dismiss from our thoughts serum therapy, vaccines and later laboratory products from which so much hope is raised, and look briefly at the one agent we have chosen to consider.

RADIO-ACTIVITY

The study of radio-activity is a wholly new science. From it has grown the realization that all matter is endowed with potential energy—atoms eternally breaking up and subject to the laws of death and decay. The instability of the ultimate atom is revealed for the first time in the discharge of electrons from atoms of radium, carrying their own charges of electricity, "if indeed, they be not electricity itself;" atoms, visible to the eye in their brilliant scintillation as they are shot into space and impinge on the fluorescent screen, or as they can be seen, diverted in the magnetic field, and weighed, timed and classified. The trained physicist accurately estimates their speed of travel, the varying electrical charge each carries, the changes they undergo and the ultimate transmutation into other elements.

Varieties of rays given off are productive of wholly different results when brought to bear on living structures. We must for the moment familiarize ourselves with the now commonly talked of *alpha*, *beta* and *gamma* rays, for we may soon learn to use them judiciously in practical work. The *alpha* are discarded; they have not been demonstrated to have any value therapeutically. They carry positive electricity on the shoulder of every atom; they can be sifted out by paper or by the glass wall of the tube containing radium and are better set aside for they only serve to burn the skin. The *beta* rays, however, are acquiring importance; these carry negative electricity and can be drawn this way and that by a magnet. They constitute the greater part of the available rays from radium. Some are held back by layers of obstructing films, as of lead foil, others penetrate deeper and others very deeply into living tissues. The *gamma* rays are more powerful and swift, penetrating all minor obstacles and even several inches of metal. But they carry no electric charge that is measurable.

Experience and experiment show that the softer *beta* rays are irritating to the skin, but can be held back by interposing thin lead foil between radium and the skin, allowing only the hard *beta* rays and the *gamma* to penetrate the tissues. This preliminary note prepares us to understand somewhat the results we see in living structures. As far as it is possible to understand this mysterious force, all we know is that we are dealing with a nascent electric atom, an electron, which supplies a negative discharge to the growth we are studying.

EFFECT ON NEW CELL GROWTH

In the play of radiant energy on a mass of new cell growth in a tumor, we often see a retrograde change, as striking as the shrinking of a mimosa plant under the touch of a human finger. Is there a supply of the needed electric balance, be it positive or negative, shot into the disorderly growth, which, perhaps, by exhaustion has lost its equilibrium? Certain it is that success or failure depends on supplying a limited amount of the varied rays which we can filter out by degrees of interposed screens of lead.

---

* Oration before the Section on Surgery of the American Medical Association, at the Sixty-first Annual Session, at St. Louis, June, 1910.

It is as if one were fighting with infantry, cavalry and artillery; or as if one loaded a gun with shot of varying size; the *alpha* rays do not escape from the tube, the *beta* may penetrate the muscles at varying depths, the *gamma* go clean through; but all leave something of themselves—a part of their electric charge—and some, the *beta*, remain to undergo change, probably, as Ramsey says, to helium. This unquestioned lodgment of material particles in the tissues accounts for persistent favorable action for weeks and months after treatment, and indeed for some secondary outbursts of dermatitis, when all effects seem to have gone by.

EFFECTS ON PLANT LIFE

It is impossible to overlook the mysterious power of radium over plant life, in considering its action on animals. Who can define the difference in the vital force actuating both? Let us expose seeds to radium rays, some for two hours, some for four, eight, twelve and so on; plant them in rows, beside one row which has had no radium. Watch them grow. Soon the normal one will have grown several inches; those longest exposed will have grown only an inch. Between these limits an exact growth proportioned to exposure will be shown. In other words, the mysterious rays have devitalized or inhibited growth proportionately to their time exposure. If we expose the seeds two days they will never grow. Here, then, *is one clue to the truth* in using radium. We may decide, after this experiment, at the start of our work, that there is a definite time treatment in all use of this agent in surgery, and it remains for us to work it out for every variety of growth.

EFFECT ON EPITHELIAL STRUCTURES

Let us consider one of the most commonplace, but the most characteristic types of cell tumor, the common wart. I ask you to consider that we are to use a specific agent, and to dismiss from your mind all thought that surgery has many other agents destructive of this growth. We propose not to destroy it, but to make it destroy itself. A wart is a simple overgrowth of the cells of the papillary layer of the skin. It may appear anywhere on the body, even in most inaccessible places, under the finger nails, on the sole of the foot, tongue, lips, eyelids, vocal cords. Apply radium to it for half an hour, and it will slowly retrograde until in four weeks the parts are as if nothing had been there. No cicatrix marks the spot as when caustics are used. The disorderly cells have simply resumed their orderly life. Nothing has been done, but a short bombardment of electrons carrying negative electricity. The result is infallible, and prepares us to wonder whether other, more succulent cells than those in this horny layer of the skin, will react as well.

The epithelial layer of the skin seems particularly susceptible. The basal-cell epithelioma, even when massive, is just as ready to undergo retrograde change as the papilloma. Nothing more startling can be seen in surgery than to watch even a good-sized epithelioma slowly yield after one or two applications of a small tube containing radium, and, losing its combative energy, melt away, draw back its budding edges, lose itself in the normal structures, and having decayed away leave only healthy tissue behind.

Such a clinical picture is to be seen every day. And what has been done? The vicious cell growth has been shot through by swift moving particles, leaving something of themselves, probably, in the tissue which they pierce in their transit through space.

WHY TUMORS GROW

If we only knew why they grow! That is more of a mystery than radiant energy. There is logical evidence that in some forms of new growth the body cells have become worn out.

In elderly people we often see a crop of epitheliomas on various parts, notably the face and hands. Often these are secondary to senile keratoses. Both show failing vitality. But, paradoxical as it may seem, the weakened cells grow exuberantly instead of dying and undergoing atrophy. Is it not fair to suppose that healthy growth is sustained by a balance of energy maintained in each cell, the loss of which upsets the equilibrium of control, and disorderly growth ensues? What follows immediately on applying the rays of radium, supplying negative charges, is a return to health. If less than a correct dose is given the relief is imperfect or temporary. Hence we can say that we medicate these exhausted cells with their own tonic, the *elixir vitæ* of cell life.

If one desires to argue that a specific germ life may be actuating the diseased growth, we must answer that that cannot be disproved, as yet.

EFFECT ON GERM LIFE

Cultures of staphylococcus, colon bacillus and other bacteria grow under a thin lead protective, but are killed on the surface of a Petri plate where radium rays play on them. Moreover, a less than lethal dose changes their virulence. A *Staphylococcus aureus* will change to an *albus*. All are so modified that, it may be, the life forces of natural repair are given a chance to conquer. This opens up a field of study not yet pursued.

RESULTS OF TREATMENT

What has been accomplished in epitheliomas of all grades, ulcerated or not, when situated on the skin, is that a healing and disappearance of the growth promptly follows a correct dosage of radium rays. This I have seen endure in perfection from three to six years in several cases. In others a slight recurrence showing an insufficiency of the first dosage, is at once overcome by renewed treatment, not more surprising than that malaria will recur when too little quinin has been given.

If we could accomplish the same result on the epithelial cancer of the wet surfaces as on the skin we might rejoice. But no such conquest can yet be claimed. Epithelial cancer of the lip, tongue, tonsil, pharynx, inside of the cheek, esophagus, stomach, rectum and uterus, are still the *bête noire* of the surgeon in spite of radium. This generous admission has given rise to an attitude of supercilious criticism by some uninvestigating members of our profession, that radium after all is a weak agent, applicable only to a few superficial conditions, better treated by the knife. So far from this common cant representing the truth, I propose to show a growing interest has widened out its sphere of influence. Let us not forget that very small quantities have as yet been available to the general surgeon.

Now, however, in England, Germany and America, following the lead of France, the most searching inquiry is being instituted, prompted by rivalry, fortified by science and corrected by criticism.

During several years I have selected a few grave cases from my own clinic, and have had many advanced and wholly inoperable cases thrust on me by good surgeons.

Having accurate notes of every case and every application of radium made during seven years, I can summarize the total outcome of treatment of these groups briefly as follows:

SUMMARY OF RESULTS

Of the lip, I have failed to cure any case. Patients shown two years ago by French observers as seemingly cured by filtration of rays are now dead from recurrences, I am informed. Dr. Wickham, the greatest living authority, recently confessed sadly that he had as yet failed to cure permanently any case of lip cancer. Cancer inside the cheek grows as if not treated; the same is true of the tonsil.

Of lingual cancer one has to speak cautiously. First, because they must be differentiated from ulcerated or non-ulcerated papillomas of the tongue, which may simulate malignancy. Of the latter, I have promptly and permanently cured four, (a section of one had shown undoubted epithelial changes).

Second, because an ulcerated cancer of the tongue is increased by foul bacterial infection. This is modified and improved by radium treatment. I have seen a long, deep, fungating cancerous ulcer of the entire side of the tongue, referred to me by the late Dr. W. T. Bull as inoperable, so far recover as to heal and retrograde until all that remained were two small nodes on the side of the tongue, which were undoubtedly the original cancer masses, lost in the infected mass first presented for treatment. At this stage Dr. Bull (always most conservative) said it was wonderful. But the retrograde process never proceeded further, and it was not many months before the extension of the cancer pursued the usual fatal course.

Third, epithelial growths in the tongue are often complicated by old syphilitic taint. So also chronic ulcers of the lip and cheek, with leucoplakia, which will not yield to medication. Almost without exception, these yield to judicious use of radium, in part, and often wholly, with cures that have been watched from one to three years.

In considering malignant growths of the esophagus, stomach, rectum and uterus in one group, we are facing that which defies every resource of our art, for as yet radium has no complete conquest to offer that has come to my knowledge, unless retardation and temporary relief be so regarded. Experience as yet is limited and the field large. Conscientious efforts and close study may resolve some of the clouds that cover this mountain of horror and obscurity. Although I have no roseate picture to present, I can truthfully say that enough has been seen to stimulate hope. Certain it is that where cachexia and hemorrhage accompany the advanced condition, the former is apt to disappear and the latter to cease after free use of radium.

If there were needed further proofs of the specific curative action of radium on certain tumors, it can be demonstrated in two cases of pure round cell growth. One, heretofore reported, still excites my wonder.

Case 1.—A tumor had grown on the lower eyelid of a man for a year; it occupied the central part and more than half the substance of the lid. It grew forward on the skin, upward and inward, to press on the eyeball. It engulfed the entire lid, beyond all semblance of edge or surface or skin. This purple growth had resisted faithful application of Roentgent rays for six weeks, and was still growing when presented to me to decide whether radium, or a plastic operation to create a new lid, was best. I laid a tube of radium on it an hour each day for four days. Then I waited. In two weeks shrinkage began; in four weeks it had half gone, and in eight weeks no trace of it was left.

Five years have gone by and to-day it is still impossible to say on which eye the tumor had been. There is a slight nick only on the sharp edge where a piece had been cut from the tumor for original microscopic study. Otherwise the edges of the lid are sharp and normal. The polished mucous surface and the skin are absolutely restored. The lashes have grown in.

In the original section made through the mass nothing but round sarcoma cells can be seen. Where were the original cells normal to the lid, the skin, the cartilage, the glandular structure, all engulfed by and apparently replaced by the neoplasm from which they have faultlessly reassembled?

Hand in hand with this instructive history of a cure, the only pure round-celled growth submitted to radium, one of even greater interest must be studied which lures on the surgeon and pathologist.

Case 2.—Six months ago, a child of four years was brought to my office, exhausted by the presence of a tumor in the right half of the abdomen, apparently renal sarcoma. Exploration showed an inoperable tumor embedded in the side, extending from the liver to the pelvis and from the vertebræ to the ribs. Its estimated weight was over four pounds. I inserted eight hollow thin celluloid tubes into different parts of the growth, into two of which strongest radium was placed. The others were for the time "dummies." Every six hours a dummy was replaced by a radium tube, so that even radiumization was obtained through the mass. During the succeeding month rapid gain in health followed. In two months the child was walking and eating and apparently restored to fine health and color, with shrinkage of the tumor in three months to one-sixth its former size. At five months I again cut away a central piece for examination and inserted radium hoping to further destroy the growth. It is too soon to say that beneficial reaction may not follow, but extension in mesenteric lymphatics is progressing slowly and not now controlled by radium.

Examination of the first pieces of tumor removed before radiumization showed massive small-cell sarcoma, with only a few scattered nerve cells; while after three months no small-cell sarcoma tissue remains, but nerve cells only. This agrees with gross appearances. The first section was a highly vascular purple mass; the second revealed a pale, inert, entirely altered tissue. In brief, though radiumization seems to have caused retrograde change of all the round-cell sarcoma, there is left neuroma structure in what was a teratomatous type of growth.

In these two cases we have seen a selective and alterative action antagonistic to a special type of new growth. But we stand more amazed at its unquestionable specific action against another type of highly specialized but destructive tumors, the giant-cell, or myeloid sarcoma. Six years ago I reported a restoration to health—through the application of radium only—of a young man's jaw, which had been in part destroyed by a soft giant cell growth. That patient remains absolutely cured to-day, with complete return to solid bone and with teeth firmly fixed in it.

During six years I have treated fourteen cases of giant cell growth by radium; with uniform demonstration of its selective action in causing retrograde changes. The first eight treated during the first three years remain as cured, though two have died of other causes, one and two years after perfect cure. The remaining six are too recent to report yet as cured, but show such characteristic change as to be probably included in future reports. The first ten I have reported in a paper read last winter.[1] Suffice it to say, a powerful and unique selective action against pure myeloid tumors can be seen when subjected to radium irradiation.

Again, there has been demonstrated a similar response, in a specialized type, of embryonic vascular tissue, nevoid growth. It is due to the assiduous and masterly work of Dr. Louis Wickham of Paris that several hundred cases of all forms of birth marks, from port-wine stains to deep angiomata, have been shown to yield results unparalled in surgery. Their shrinkage in size and return to a nearly normal color of skin, without destructive cicatrix (unless the treatment be overdone) has demonstrated in the hands of Wickham and De Grais a specific alterative and restorative action in this embryonic type of tissue, that adds another claim to the specific action of radium on endothelial growth, which shrinks the mass and obliterates without destruction of tissue. I have seen many of these beautiful results in the hands of these masterly French workers, which, however, will long challenge equality in less experienced ones.

EXPERIMENTAL

Finally a trial of this unique agent has been given in a large variety of morbid conditions, and necessarily in rather a desultory way, as leaders for research. It has been demonstrated beyond question that it exerts a beneficent action on many varieties of glandular hyperplasias, notably on some goiters. Two or three out of some fourteen remain cured from three to six years. Also, on parotid sarcomas, in which, of all surgical conditions, we need more efficient surgical help. In trachoma and obstinate vernal catarrh also there have been demonstrated some brilliant cures. In short, there has been shown the existence of a subtle force latent in radium, resembling that in Roentgen rays, but unlike it and supplemental to it, with specific action for certain cells found in specialized tumors, which causes retrograde degeneration and atrophy.

The cases are not yet sufficiently numerous nor long enough studied to classify in groups warranting definite promise of uniform results. The careful scientific study by four radium institutes now established in France, Germany, England and America promises ultimately to clear the atmosphere of doubt, and formulate definite rules guiding its correct usage.

13 West Fiftieth Street.

Teratoma of the Ovary with Carcinomatous Changes.—A solid ovarian tumor was removed from a child 12 years of age (Martland, *New York Path. Soc. Rep.*, December, 1909). Two weeks previous to admission the patient had sharp, stabbing pains in the abdomen, later becoming localized in the right side, accompanied by nausea and vomiting. A diagnosis of appendiceal abscess was made and the abdomen opened. The tumor was removed a week later. Adhesions to the abdominal wall and the omentum caused troublesome bleeding. The left ovary at the first operation showed no tumor but at a third operation was as large as an orange. The child died several weeks later with numerous nodular masses in the abdomen. On gross section a large portion of the tumor looked like myxomatous tissue. There were considerable areas of smooth muscle and many cysts lined with cuboidal and low cylindrical cells, containing blood or serum. In some parts typical glandular structures occurred, formed of a single layer of cylindrical cells. No cartilage, nervous tissue, fat, striated muscle or bone were found. After considerable study by the Pathological Society the above pathology was determined.

PURPURA CAUSED BY THE INGESTION OF THE IODIDS*

FRANK CROZER KNOWLES, M.D.
Assistant Dermatologist to the Philadelphia Hospital; Dermatologist to the Dispensary of the Children's Hospital, to the Church Home for Children, to the Baptist Orphanage; Associate Dermatologist to the Dispensary of the Howard Hospital; Assistant Dermatologist to the Dispensaries of the Pennsylvania and the University of Pennsylvania Hospitals
PHILADELPHIA

Because of the numerous types of eruption that may be produced by the ingestion of the iodids the subject is fraught with the greatest interest. Very few lesions of the skin have not been caused, at one time or another, by small or large doses of iodin or its various salts. Hundreds of papers have been written on the subject as a whole or on some interesting phase of it. The literature is so large that I am compelled to limit my remarks to the eruptions of the purpuric type.

Although it is frequently difficult to ascertain accurately its past history in medicine, Coindet[1] was apparently the first to introduce iodin into the practice of medicine as a therapeutic agent. Ricord,[2] in 1839, mentioned various cutaneous eruptions that were caused by the ingestion of potassium iodid; the same author,[3] in 1842, referred to several cases in which he had seen the same drug produce a "veritable purpura hemorrhagica"; the purpuric eruption not having been mentioned in his first communication. Zeissl[4] stated that he had seen in very rare cases ecchymoses and telangiectases in the form of nevi, of the size of the head of a pin, produced by the administration of the salts of iodin. Cazenave[5] was the first to record the occurrence of bullous lesions, with sanguinolent serum, followed by ulcerations difficult to heal, caused by the ingestion of potassium iodid. The most complete papers written on the subject of iodism and the various eruptions caused by the absorption of iodin and its various salts have been compiled by Petitjean[6] and Bradley.[7]

I have been able to obtain references in the literature to eleven bullous and fifty non-bullous cases, all of the hemorrhagic type, exclusive of the two petechial cases reported in the present paper. Mora[8] and Welander[9] have also written papers on this subject, reporting cases of the purpuric type, but I have been unable to consult the articles.

HEMORRHAGIC BULLOUS CASES

Sex.—Four of the cases with hemorrhagic bullæ occurred in women (Pusey,[10] Elsner,[11] Broadbent,[12] Taylor[13]); five in men (Russell,[14] Gottheil,[15] Morrow,[16] Bumstead,[17] McGuire[18]); and two in children, the sex being unspecified (Hudelo and Lebar,[19] Hallopeau and Lebret[20]).

Age.—The youngest case reported of the hemorrhagic bullous type, occurred in a child of 10 years (Hallopeau and Lebret[20]); another developed under the age of 20 years (Hudelo and Lebar[19]); one patient showed the idiosyncrasy at 28 years (Bumstead[17]); another at 39 years (Broadbent[12]); one patient was attacked at 45 years (Gottheil[15]); another at 49 years of age (Elsner[11]); one at 50 years (Morrow[16]); one at 51 years (McGuire[18]); and the ninth, at 68 years of age (Russell[14]). The ages of two of the patients were not mentioned (Pusey,[10] Taylor[13]).

---

[1] Radium as a Specific in Giant-Cell Sarcoma, Med. Rec., New York, Jan. 1, 1910, p. 1.

* Read in the Section on Dermatology of the American Medical Association, at the Sixty-first Annual Session, held at St. Louis, June, 1910.

Cause of Administration.—In four of the eleven cases, the drug was administered for syphilis (Bumstead,[17] Gottheil,[15] Hallopeau and Lebret,[20] Hudelo and Lebar[19]); in pneumonia (McGuire[18]); in Bright's disease (Broadbent[12]); for rheumatism (Russell[14]); for a "cold" (Elsner[11]); and in three cases the disease for which the drug was prescribed was unspecified (Morrow,[16] Taylor,[13] Pusey[10]).

Length of Administration and Quantity of Drug Given.—The quantity of the drug and the length of administration varied considerably in the eleven cases with sanguinolent bullæ; in some but a few small doses produced the outbreak while in others hundreds of grains of potassium iodid were ingested before the point of intolerance was reached. In Bumstead's[17] case the eruption appeared after taking three 20-grain doses of potassium iodid; the outbreak was noted in Taylor's[13] case after 1 dram had been ingested; hemorrhagic bullæ appeared on Elsner's[11] patient after nine doses of potassium iodid had been administered, grains four having been given every six hours; McGuire's[18] patient took a total of 20 grains of the ammonium iodid in 1¼-grain doses; the eruption appeared in Broadbent's[12] case after taking potassium iodid in 3-grain doses during a period of five days; Pusey[10] prescribed for his patient 7½ to 10 grains of potassium iodid three times daily; Russell's[14] patient took 15 grains of iodin in three days; Morrow's[16] patient received 900 grains of potassium iodid in the space of ten days; Gottheil[15] administered 100 grains of potassium iodid daily for six days; Hallopeau and Lebret[20] produced the eruption experimentally on giving 3 gm. of potassium iodid. The dose or the quantity of the drug prescribed was not mentioned by Hudelo and Lebar.[19]

Character of Eruption.—The eruption was multiform, chiefly, however, consisting of hemorrhagic bullæ in Morrow's[16] case. Gottheil[15] recorded the presence of hemorrhagic vesicles and bullæ. Hemorrhagic bullæ with subsequent ulcerations were noted in three cases (Taylor,[13] Russell,[14] McGuire[18]). Pusey[10] reported the occurrence of sanguinolent bullæ, ulcerative and gangrenous areas in his case. In Bumstead's[17] case purpuric spots, clear and hemorrhagic bullæ, and ulcerations were all present. Elsner[11] recorded the presence in his patient of hemorrhagic and clear vesicles and bullæ, wheals, and nodular lesions. Hallopeau and Lebret[20] reported a remarkable case, in which hemorrhagic vesicles and bullæ, macular petechiæ, infiltration plaques, papillomatous lesions, and callous areas were produced by the ingestion of potassium iodid. Hudelo and Lebar's[19] patient exhibited large ecchymotic areas, small petechiæ, hemorrhagic bullæ, and a tuberculid of an angiokeratoma type was also present.

Distribution.—The arms, the hands, the face and the legs were attacked in the cases of Broadbent[12] and Gottheil.[15] The lesions were limited to the face, the hands, and the forearms in Morrow's[16] and Elsner's[11] cases. The feet, the lower legs, the face and the hands were involved in Bumstead's[17] patient. Taylor[13] noted the eruption on his patient on the face, the arms and the gluteal region. The face, the shoulders, the groins, the back, and the scalp were attacked in McGuire's case.[18] The face, the scalp, the neck, the chest, the arms and the legs were involved in Russell's[14] case. Hudelo and Lebar[19] reported the involvement of the arms, the neck, the legs and the feet. The distribution was generalized in the case reported by Hallopeau and Lebret.[20] Pusey[10] did not mention the distribution of the eruption.

PURPURIC NON-BULLOUS CASES

Sex.—Ten cases occurred in patients of the female sex (Fournier,[21] Cruveilhier,[22] Silcock,[23] Walter Smith,[24] Morrow,[25] Janovsky,[26] Labat,[27] Waren Tay,[28] Barlow,[29] Raymond[30]); twenty-two developed in the male sex (Ringer,[31] Debuchy,[32] Robinson,[33] Bradbury,[34] Duckworth-Gee,[35] Bernart,[36] Fournier,[21] and Suchanek,[37] each two cases, Ricord,[3] Duffy,[38] Barton,[39] Neumann,[40] Petitjean,[41] Payen,[42] Lemoine,[43] J. H. Wilson,[44] Colcott Fox,[45] Abbe,[46] Hoening,[47] Vidal[48]); and the sex in eighteen cases was not specified (Mackenzie,[49] Petitjean,[50] Virchow,[51] Neumann,[52] Pernet,[53] two cases, Fournier,[21] twelve cases).

Age.—The youngest case reported occurred in a child of 5 months (Mackenzie[49]). Ringer[31] reported a case at 17 years; Janovsky[26] one at 22 years; Petitjean's[41] was noted at 23 years of age; Suchanek's[37] patient developed the eruption at 24 years; Duffy's[38] patient showed the outbreak at the twenty-fifth year; the case of Duckworth-Gee[35] developed at 29 years; four cases were recorded at 30 years of age (Fournier,[21] Neumann,[40] Colcott Fox,[45] Abbe[46]); Bernart,[36] reported a case at 31 years; Lemoine's[43] occurred at 32 years; Barton,[39] noted his case at 35 years; Walter Smith[24] observed his patient at 39 years; the outbreak developed in Barlow's[29] patient at the forty-second year; Labat's[27] case showed the exanthem at the forty-third year; the eruption appeared in Waren Tay's[28] patient at the age of 44 years; the outbreak in Suchanek's[37] second patient occurred at the forty-sixth year; the eruption appeared in Vidal's[48] case at 50 years of age; a case reported by Raymond,[30] developed at 53 years; Bradbury's[34] patient was 58 years old when the eruption appeared; the outbreak attacked Robinson's[33] patient at 53 years of age; Hoenning reported the case of the oldest patient (aged 64) in whom the eruption appeared. The age of the patients on whom eruption of petechiæ and ecchymoses developed were not mentioned by Fournier,[21] fourteen cases, Pernet,[53] two cases, Ricord,[3] Cruveilhier,[22] Silcock,[23] Petitjean,[50] Morrow,[25] Payne,[42] J. H. Wilson,[44] Neumann,[52] Virchow,[51] Debuchy.[32]

Cause of Administration.—The drug was administered for syphilis in eighteen cases (Bernart,[36] Fournier,[21] three cases, Cruveilhier,[22] Silcox,[23] Suchanek,[37] two cases, Walter Smith,[24] Petitjean,[50] Janovsky,[26] Payen,[42] Barlow,[29] Colcott Fox,[45] Abbe,[46] Hoening,[47] Vidal,[48] Mackenzie,[49]). It was given in the treatment of rheumatism in eight cases (Duffy,[38] Labat,[27] Lemoine,[43] J. H. Wilson,[44] Raymond,[30] Bradbury,[34] Ringer[31] Debuchy[32]). The iodid was given in one case for paralysis (Barton[39]); for leprosy in another (Pernet,[53]) for atrophy of the optic disc in a third (Waren Tay[28]); for uratosis in one case (Robinson[33]); and in another for cancer (Virchow[51]). The indication for the use of the drug was not specified in nineteen cases (Fournier,[21] twelve cases, probably given for syphilis, Duckworth-Gee,[35] Ricord,[3] Petitjean,[41] Pernet,[53] Morrow,[25] Neumann,[40, 52] two cases).

Length of Administration and Quantity of Drug Given.—Mackenzie[49] described a case in an infant of 5 months in which the eruption appeared in three-quarters of an hour, after 2½ grains of potassium iodid had been given. In Colcott Fox's[45] case the eruption developed after two doses of 5 grains each, of potassium iodid had been administered about six hours apart. Three 5-grain doses of potassium iodid caused the outbreak in the case reported by J. H. Wilson.[44] In Robinson's[33] case potassium iodid was given in grain doses three times daily; the eruption occurred after six days of medication. The outbreak appeared in a few days in Labat's case[27] after giving 3-grain doses. Lemoine[43] prescribed 1 gm. of sodium iodid daily; the next day the eruption appeared, twenty hours after the drug was administered. Ringer[31] gave his patient 10 grains of potassium iodid three times each day; the rash appeared in five days. Waren Tay[28] produced the eruption on prescribing 1.5 gm. of potassium iodid daily. Petitjean[50] gave between 3 and 4 gm. of potassium iodid daily; the outbreak occurred in four days. Abbe[46] prescribed 10 grains of potassium iodid three times daily; the eruption appeared after two weeks' administration. Raymond[30] gave 50 cg. of potassium iodid in two doses daily; after ten days the dose was increased to 1 gm. daily; the outbreak occurred after 8 gm. of the drug had been ingested. In Vidal's[48] case 15 grains of potassium iodid were given three times each day; the exanthem appeared after the drug had been taken for three weeks. Barlow[29] ordered 1 gm. of the drug to be given daily; at about the third week the potassium iodid was increased to 1.5 gm. each day; two days later the rash developed. The eruption appeared in Janovsky's case[26] after 24 gm. had been administered; 2 gm. sodium iodid having been given daily. Hoening[47] prescribed a mixture of sodium and potassium iodids; 40 gm. of this combination were given in twenty days. Silcock[23] gave 10 grains of potassium iodid three times a day; the dose was increased after fifteen days to 15 grains three times daily; seven days later the eruption appeared. Duffy[38] prescribed for his patient 10 grains of potassium iodid three times each day; the dose was increased three weeks later to 15 grains three times daily; 2½ ounces of the drug were given; the outbreak occurred in one month's time. Suchanek[37] gave a total of 42 drams in one case and 23 drams of potassium iodid in the other. In Duckworth-Gee's[35] case 50 cg. were given daily; 6 gm., in all, were ingested. In Payen's[42] case the eruption appeared after two months treatment with the iodid of iron. The eruption occurred after administering potassium iodid for five days in Bernard's case.[36] Moderate doses of potassium iodid were given in Fournier's[21] three cases; the purpuric spots appeared in one week, five days, and a few days, respectively. The rash appeared after a few doses in Debuchy's case.[32] The outbreak occurred in Ricord's[3] case after potassium iodid had been given for fifteen days. After the drug had been given but a few days the exanthem appeared in the case reported by Walter Smith.[24] The eruption appeared on Barton's[39] patient in three weeks' time, small doses of potassium iodid having been prescribed. The dose of the drug and the length of administration were not mentioned in twenty of the cases (Cruveilhier,[22] Neumann[40, 51] and Pernet,[53] each two cases; Petitjean,[41] Bradbury,[34] Virchow,[51] Fournier,[21] twelve cases).

In a few instances the eruption appeared some days after the drug had been discontinued. Suchanek[37] recorded a case in which the eruption appeared eight days after the iodid had been stopped. In the hemorrhagic bullous case reported by Morrow[16] the eruption did not reach its height until five days after the potassium iodid had been intermitted. In the case with hemorrhagic bullæ recorded by McGuire[18] the lesions continued to appear for ten days after the drug was discontinued. Broadbent[12] also recorded the fact in his hemorrhagic bullous case that the eruption continued to appear for six days after the potassium iodid had been stopped. The purpuric exanthem continued to appear for eight days in one of Suchanek's[37] cases, and for twenty-six days in the other. Outbreaks of purpura from the iodid continued for ten days in Janovsky's[26] patient, and for three weeks in Raymond's[30] case.

Type of Eruption.—In all of the non-bullous cases, except five, the eruption was entirely purpuric in type. The lesions were mostly from small to large pinhead in size; in Hoening's[47] case, however, some of the ecchymoses were one-quarter dollar in dimensions. Duckworth-Gee[35] described, in the case reported, a herpetic eruption with a purpuric areola. In Neumann's[40] patient the eruption was chiefly papillomatous or pustular; some of the lesions were petechial. In one of the two cases reported by Petitjean[41], with purpuric lesions, the predominant type consisted of furuncles and pustules. Vidal[48] noted in his case a papular outbreak on the trunk and a purpuric eruption on the legs. The outbreak in Debuchy's[32] case consisted of a vesicular as well as a petechial eruption; an eczema was also present.

Distribution.—The eruption was, in a great majority of the cases, localized to certain portions of the body, chiefly the lower extremities. The eruption was generalized in Hoening's[47] case. The outbreak was generalized, excepting the chest, the back, and the hairy scalp, in Neumann's[40] patient. The upper and lower extremities and the shoulders were attacked in the case reported by Mackenzie.[49] There was extensive involvement in Lemoine's[43] case; the thighs, the abdomen, the lumbar region, the chest and the arms are the areas attacked. The entire face, the forearms and the neck were the areas of predilection in Duckworth-Gee's[35] patient. The scrotum, the thighs and the legs were involved in Bernart's[36] case. The upper and lower extremities were attacked in two cases (Janovsky,[26] Bradbury[34]). The forearms and the lower portion of the legs were involved in three cases (Colcott Fox,[45] Abbe,[46] Robinson[33]). Raymond's[30] patient showed the lesions distributed on the arms, the hands and the legs. The hands and the legs were the seats of attack in the case recorded by Debuchy.[32] J. H. Wilson[44] noted the distribution in his patient on the lower legs, and the dorsum of the feet. The eruption was limited to the lower abdomen in one case, and attacked the lower abdomen and the extremities in the other case of Suchanek's.[37] The lower extremities alone were attacked in eight cases (Cruveilhier,[25] Silcox,[23] Barton,[39] Waren Tay,[28] Vidal,[48] Ringer,[31] Petitjean,[41, 50] two cases). The eruption was limited to the lower portion of the legs in twenty cases (Duffy,[38] Ricord,[3] Walter Smith,[24] Payen,[42] Labat,[27] Barlow,[29] Fournier,[21] fourteen cases). In one of Fournier's[21] fifteen cases, the outbreak was not only found on the lower legs but lesions, purpuric in type were also scattered on the trunk. The distribution of the eruption was not specified in five cases (Morrow,[25] Neumann,[62] Virchow,[51] Pernet,[53] two cases).

Mild symptoms of iodism preceded or accompanied the eruption in several of the cases, notably in those reported by Petitjean,[50] Janovsky,[26] Barlow,[29] J. H. Wilson,[44] and Debuchy.[32] Severe symptoms of iodism were observed in Mackenzie's[49] and Raymond's[30] fatal cases.

Edema of the glottis was caused by the drug in two of the cases (Petitjean[50] Neumann[52]). Several authors have referred to edema of the glottis caused by the ingestion of potassium iodid. Nelaton,[54] Lawrie-Adair,[55] and Fenwick[56] have reported cases of this character. Weist[57] recorded an interesting history; a woman of 28 was instructed to take 50 grains of potassium iodid a day; eleven hours after the first dose was administered a generalized edema developed.

Mucous Membrane Involvement.—The mucous membranes were attacked in two of the hemorrhagic bullous cases. Hemorrhagic bullæ were found on the tongue and the roof of the mouth in the case reported by Taylor.[13] Russell[14] recorded the occurrence of bullæ filled with blood in the nares in his case. The mucous membranes were attacked in five of the non-bullous petechial cases. Purpuric spots were noted on the left conjunctiva in Duckworth-Gee's[35] patient. A hemorrhagic eruption was present on the gums in the patient of Suchanek.[37] Numerous ulcers were found on the walls of the stomach near the pylorus in Neumann's[52] patient, supposedly caused by the ingestion of potassium iodid. The roof of the mouth exhibited petechiæ in Hoening's patient,[47] and on the hard palate in the one reported by Mackenzie.[49] Milain[58] described a case in which ecchymotic spots were found on the palate, which appeared on starting the drug and disappeared on stopping the same. There was a papulopustular eruption on the face, the back and the limbs caused by the potassium iodid, but there were no purpuric lesions on the cutaneous surface.

Hemorrhage from Mucous Membranes or Organs.—Boinet[59] in 1865 mentioned the fact that the ingestion of iodin may cause hemorrhage from the lungs and the intestines. Rodet[60] recorded an interesting case in which a man of 35 was attacked by hemoptysis whenever potassium iodid was given. DeBolze[61] reported an instance in which a blood-tinged cough was produced whenever the iodids were given; no signs of phthisis were present. Lindsay[62] referred to a case in which a woman of 58 after taking a few doses of potassium iodid developed the catamenial flow, which had been absent for twelve years. This flow continued for the entire week during which the drug was given. The administration of the iodid also caused symptoms of iodism and a bullous, non-hemorrhagic eruption.

In the present series two of the hemorrhagic bullous cases and five of the petechial, non-bullous cases exhibited phenomena of this character. Hemoptysis was noted in Broadbent's[12] case. Elsner's[11] patient vomited blood and passed the same by the rectum. Epistaxis and bleeding from the gums were noticed in the case reported by Duckworth-Gee.[35] Cerebral hemorrhage was present in Neumann's patient; whether caused by the drug or from some other condition is not clearly stated by the author. Epistaxis was caused by the drug in the cases recorded by Janovsky,[26] Bradbury[34] and Abbe.[46]

Organic Disease Present at the Time of Administering the Iodid.—Heart or kidney disease, one or both, were present at the time the drug was administered in four of the cases which developed the hemorrhagic bullous lesions, and in six of the non-bullous cases. Disease of both the heart and kidneys were found in Morrow's[16] and Gottheil's[15] patients. Disease of the kidneys was found in the case recorded by McGuire.[18] Broadbent's[12] case exhibited nephritis, pericardial trouble and a pleuritic condition of the lungs. Nephritis was discovered in the two cases reported by Neumann[40, 52]. Valvular disease of the heart was present in the case recorded by Duffy.[38] Nephritis and valvular disease of the heart were found in Lemoine's[43] and Pernet's[53] cases. Pericarditis, congestion of the lungs, aortic and mitral lesions, hypertrophy of the heart, and disease of the kidneys were all noted in Duckworth-Gee's[35] patient

CASES OF THE AUTHOR

Case 1.—Helen L., aged 27, born in Germany, came to the skin dispensary of the Pennsylvania Hospital, April 13, 1906. There were no derangements of the heart or kidneys present, and her past history was negative. A few weeks previous to her visit to the dispensary she obtained a mixture at a drug store for pains in her muscles and joints. The patient stated that the mixture contained potassium iodid. After taking the preparation for some weeks, ten days before coming to the dispensary an eruption appeared on the lower extremities. The lesions were limited to the lower extremities, extending from the upper thighs to the ankles, and consisted of bluish and reddish-blue, pinhead to split-pea-sized macules, from which the color could not be pressed. The eruption disappeared a few days after stopping the medication. To prove whether or not the iodid was the etiologic factor, one week after the disappearance of the lesions the drug was again given. Potassium iodid was given in 10-grain doses three times daily; on the second day 11 grains were given at a dose, on the third, twelve grains three times during the day, and the administration was continued in the same ratio. When the dose had been gradually raised in this manner to 17 grains three times daily, a purpuric eruption developed with the same characteristics and distribution as the first outbreak, previously described.

Case 2.—Mary H., a very light mulattress, aged 40, born in North Carolina, came to the skin dispensary of the Pennsylvania Hospital, July 13, 1906. The patient had previously been treated in Dr. Morris Lewis' ward at the Pennsylvania Hospital for aneurism and aortic insufficiency. No history of rheumatism could be obtained. The urine contained no albumin or casts. The patient was given 10 grains of potassium iodid, three times a day. The drug was started April 15 and continued until the patient's visit to the dispensary. A few days before she came to the skin dispensary the eruption appeared on the legs. The purpuric lesions were large, pin-head in size and limited to the tibial aspect of the lower legs. The eruption disappeared a few days after the drug was stopped. One week after the disappearance of the lesions the drug was again given. Five grains of potassium iodid were administered three times daily. After the drug had been taken for twenty days the purpuric eruption again appeared on the same areas as previously exhibited the outbreak.

Potassium iodid is not the only salt of iodin that may produce an eruption, as the outbreak was produced in Lemoine's[43] patient by sodium iodid and also in the case reported by Janovsky.[26] The iodid of iron was causal in Payen's[42] case. The eruption was caused in Hoening's[47] patient by a combination of the sodium and the potassium iodids. Both the ammonium and the potassium iodids, separately, produced the outbreak in Duffy's[38] and Ringer's[31] cases. The latter writers however, reported negative results with the sodium iodid.

The same individual may have an idiosyncrasy to more than one drug. Raymond[30] found that his patient had also a marked intolerance for 5 cg. of santonin, and for 2 gm. of sodium salicylate.

Pathology.—Tilbury Fox[63] believes in the follicular and sebaceous gland origin of all types of iodid eruption. Fox and Gibbes[64] found that the small arteries were blocked and the vessels were affected in every section examined by inflammatory changes. Engman and Mook[65] found in the examination of papules, pustules and macules from numerous cases of iodid eruption that the sebaceous glands and the follicles were not primarily affected by the drug, practically all of the changes occurring in the neighborhood of the blood vessels. Thin[66] found in the acne form of eruption, caused by the ingestion of potassium iodid, limited edema with congestion of the vessel; in the bullous or pustular form an effusion of serum with more or less of the formed elements of the blood, and in the purpuric type destruction of the wall of the vessel and hemorrhage. Thin[66] *points out the tendency of iodin* when present in the blood current to *attack* special points of the vessels, thus explaining all the varieties of eruption caused by iodin. As an explanation of the purpuric eruption he suggests that a portion of the vessel is so suddenly and completely destroyed that the local changes are limited to effusion of a small quantity of pure blood, and to plugging of the vessel. The specimen examined by Thin[66] showed the changes limited to a small part of the vessel, which was dilated at that spot and blocked by coagulum. Duckworth and Harris[67] found the blood vessels were very numerous in *all of the specimens* examined. The sebaceous gland origin of the various types of iodid eruption can probably be excluded, as most authorities do not agree with the original findings of Tilbury Fox.[63] As Biesiadecki[68] *and others have never been able* to demonstrate the presence of either sebaceous glands or lanugo follicles on the palms of the hands, and as Duhring[69] and Hyde[70] have each reported eruptions from potassium iodid on this area, the sebaceous *origin of the outbreak* is evidently disproved.

Absorption and Elimination.—Arnozan and Carles[71] have gathered together in an excellent paper the facts regarding the role the leucocytes play in the *absorption* of certain medicines, including iodin. The latter phase of the subject has been particularly studied by Stassano and Bourcet.[72] The leucocytes absorb the iodin and carry this drug, with which they are charged, to different tissues or organs of elimination. The drug absorbed may undergo various changes in the leucocytes, being transformed by the action of various ferments which these cells contain. The drugs may be stored by these cells at various points and thus give rise, under various circumstances, to a pathologic effect. Ménière,[73] after a great many experiments, *concluded* that the time required for the absorption of the salts of iodin and their elimination by the salivary glands is on an average from eight to ten minutes; when the stomach is full the elimination is retarded *from* thirty to forty minutes. If the stomach is absolutely empty and the potassium iodid is given in a warm liquid of some stimulating power, such as tea, elimination may be detected *in the* saliva in from two to three minutes. According to this same investigator absorption of this drug occurs most rapidly by the bronchial mucous membrane; it takes slightly less than double the time for absorption to occur by the stomach and the esophagus as by the bronchial mucous membrane. Quincke[74] found the presence of iodin in the small intestine, the saliva, the urine, the serum of the blood and in the aqueous humor, but not in the stomach or the large intestine, one and one-quarter hours after a hypodermic injection of the drug had been given; while it took almost two and one-half hours to produce the same results *after* ingestion through the stomach.

Iodin has been found in the urine in several of the cases in this series, Janovsky[26] noted the reaction for the drug for six days after the medication had been stopped; iodin was found in the urine in Pusey's case.[10] Berg[75] gave a venous injection of from one hundred to one hundred and thirty grains of potassium iodid in animals and iodin was found in the urine after fifteen minutes had elapsed. Marshall[76] recovered 265 grains daily in a case of Wood's, in which 360 grains of potassium iodid were taken daily. According to Sée,[80] the reaction to the drug may exist in the saliva after it has disappeared from the urine.

Adamkiewicz[77] mixed the pus from the pustules caused by the ingestion of the iodid with starch and *added* a few drops of very dilute nitric acid, and obtained the reaction of iodin. The *test for iodin* in Gottheil's case proved negative. Engman and Mook[65] in a valuable series of experiments on numerous patients with *various types* of iodid eruption proved the elimination of iodin through the skin. They *found a positive* reaction of the pus in every case examined, iodin being distinctly present. Skin free from any lesions, although *an iodid eruption* was *present* on other portions of the body, was blistered by them in two cases and the serum from these blisters was investigated. In each instance iodin was readily discovered, thus proving that iodin occurred in *chemical combination* in all the tissues of the body. Taylor[78] believes that iodin is eliminated in certain cases by the sweat-glands, citing a case to prove this assertion.

Prognosis.—The administration of the iodids, particularly in large doses, to those individuals who have a strong idiosyncrasy to the drug, or in cases with organic *disease of the heart or the kidneys, is frequently* a dangerous procedure. Seven out of the eleven hemorrhagic, bullous cases ended fatally, and two of the nonbullous, petechial type. Elsner's[11] patient died five days *after the drug was started!* Russell's[14] patient succumbed on the tenth day after the drug was first given. The patient whose case is reported by Pusey,[10] died ten days after the appearance of the eruption. The *termination* was fatal in Gottheil's[15] case, seventeen days after the medication was commenced. Broadbent's[12] case ended fatally three weeks after the drug had been given on a second trial. Morrow's[16] and McGuire's[18] patients died six weeks after the drug was first administered. Mackenzie's[40] case proved fatal sixty-eight hours after one dose, 2½ grains of potassium iodid, had been *given to a child of five months.* In Duckworth-Gee's[35] case, the patient died on the tenth day after the drug had been started.

Fournier[21] has had more opportunity to study purpura caused by the ingestion of potassium iodid than any other observer, as he has reported in one series fifteen cases. According to his observations, if the drug is given in the same moderate dose over an uninterrupted period the purpuric eruption produced by the potassium iodid is apt to lessen in severity until there is an almost complete disappearance, even while the small dose of the drug is continuously given; if, however, the dose of the drug is considerably increased, a fresh outbreak will occur which is usually not so severe as the first attack. If the drug is stopped for a few weeks, and the same small dose is given as in the first instance, an eruption will again be produced but the outbreak is usually not so severe as the lesions first caused by this small dose. *The experience* of Fournier[21] has coincided with the observation of more recent writers on the subject. A certain tolerance, therefore, seems to be formed to the drug in a great many individuals who are *susceptible to this medication*, but the tolerance is but transitory, as the increase of the dose, while the drug is being taken in moderate quantities, will produce a fresh outbreak, or if the drug is stopped for but a few days the tolerance is lost and the original dose, or even a smaller quantity, will again produce the eruption.

The decreased dosage causing the eruption is well exemplified in the bullous, non-hemorrhagic case described by Besnier,[79] in which the outbreak was first caused by 2 gm. of potassium iodid, on a second occasion by 1 gm. and a third time by 10 cg. The eruption was first produced in Duffy's[38] case by 2½ ounces of potassium iodid, and on another occasion by 15 grains. In Abbe's[40] case the eruption was produced on six different occasions, each time less of the drug being required to cause the outbreak; the eruption first appeared after 10 grains of potassium iodid, three times daily, had been given for two weeks; the fifth and the sixth attack was caused by three and by two 5-grain doses respectively. The eruption was at first caused in Raymond's[30] case by giving 8 gm. of the drug, in divided doses, the second outbreak was induced by administering 3 gm. in five days. On the first occasion the exanthem appeared in Ringer's[31] case after 10 grains of potassium iodid three times each day had been given for five days, the eruption was reproduced by prescribing four 10-grain doses of the drug. The outbreak first occurred in McGuire's[18] case after 20 grains of ammonium iodid had been given; on a second occasion 5 grains sufficed to produce the hemorrhagic bullæ. The administration of 1.5 gm., of potassium iodid in Waren Tay's[28] patient produced the eruption on five different occasions in nine weeks. In one of my cases the eruption was reproduced by one-half of the dose of the drug and in one-quarter the length of time required for the first outbreak.

After a careful study of sixty-three cases of purpura caused by the ingestion of potassium iodid, eleven being of the hemorrhagic, bullous type, I feel justified in making two provisional groups of these eruptions. In the first group may be placed all those cases in which there is some organic disease, some lowered condition of the general economy which makes the individual more susceptible to the effects of the drug, and those with a strong idiosyncrasy to the iodid. The bullous eruptions of the hemorrhagic type and the petechial cases with a somewhat generalized outbreak should be classed in the first group. In the second group the patient is found in the best of health, and there is absolutely no way of explaining the outbreak except on the hypothesis of a mild idiosyncrasy to the drug. In this latter group should be placed the purpuric cases with a very localized distribution, which have the tendency to remain limited, particularly to the lower portion of the legs. Fournier's[21] fifteen cases should be taken as the type of case belonging in the second group. There is probably no doubt that in the localized cases of purpura, caused by the iodids, in which small doses of the drug have been administered, the eruption may be made general and severe if the drug is continued in very large doses over a long period of time. The drug should be used with the greatest care in those individuals with some organic lesion, in whom the general condition is below par, and as a safeguard the beginning dose should be small, as a strong idiosyncrasy to the iodid may be present.

SUMMARY

Purpuric eruptions caused by the ingestion of the iodids may be divided into two provisional groups.

The first group includes the extensive petechial and hemorrhagic, bullous cases, which occur in those individuals with organic disease, particularly of the kidneys or the heart, or with a lowered condition of the general economy, making them more susceptible to the effect of the drug, or with a strong idiosyncrasy to the same.

The second group includes all cases with a localized distribution, particularly those in which the eruption is limited to the lower extremities or the lower legs, which occur in those individuals in perfect health, and which can be explained only on the theory that a mild idiosyncrasy to the iodid is present.

Sex and age have nothing to do with the occurrence of the eruption, although most of the cases developed during middle life, and a considerably larger percentage of males were attacked than females.

The drug was administered in twenty-two of the sixty-one cases for syphilis, for rheumatism in nine cases, and in the remainder in numerous other conditions, none of which apparently exerted any predisposing influence.

The quantity of the drug given and the length of administration varied so markedly that an average dose or the length of time of continuance cannot be stated, the personal element alone deciding the question of an eruption.

The eruption was chiefly of one type, either the petechial or the hemorrhagic bullous, although in a few cases other forms of iodid lesions were present.

In the hemorrhagic bullous cases, although in several the eruption was somewhat generalized, the face and the extremities were mostly involved, particularly the face and the arms.

In the petechial type the eruption in a great majority of the cases was limited to the lower extremities, particularly the lower portion of the legs; in a few cases, however, the outbreak was somewhat generalized or noted on the upper as well as the lower extremities.

Mild symptoms of iodism were present in a few cases, and severe reaction to the drug was noted in two cases. Edema of the glottis was found in two instances.

Lesions were found on the mucous membranes in a few cases; hemorrhages occurred from the mucous membranes or from various organs in a few others.

Organic disease of the kidneys and the heart were found in but few—ten out of sixty-one cases.

The various salts of iodin are all capable of causing a purpuric eruption.

The pathologic changes of the skin were noted in the immediate vicinity of the blood-vessels and in the walls of the vessels themselves.

Iodin is rapidly absorbed by all mucous and serous surfaces and rapidly eliminated, chiefly by the kidneys and also through the skin itself. The leucocytes play a distinct rôle in the absorption of the drug.

Hemorrhagic bullous cases, of extensive distribution, are frequently fatal, seven out of the eleven in this series ending fatally.

Petechial, non-bullous cases rarely terminate in death, unless there is marked disease of the heart or kidneys or a very extreme intolerance to the drug; two out of the fifty cases of this type ended fatally.

In conclusion I wish to express my thanks to Dr. Charles N. Davis for the privilege of reporting the two cases and to make a plea for smaller doses of the iodids.

332 South Seventeenth Street.

ABSTRACT OF DISCUSSION

Dr. J. A. Fordyce, New York: I do not think we ought to allow this occasion to go by without deprecating the reckless way in which potassium iodid is given, not only by the general practitioner, but by the specialist. In syphilis it is frequently given in doses of several hundred grains daily, and in the majority of those cases the same benefit could be derived from thirty, or, at most, one hundred grains daily. We are entirely too reckless in the administration of the drug, and have overlooked the fatalities that have been reported from its excessive use. In some instances, these harmful effects are due to excessively large doses; in others, to an over-susceptibility on the part of the patient. Dr. Knowles' paper also emphasizes the importance of looking into the condition of the eliminative organs before we resort to large doses of potassium iodid.

Dr. Howard Fox, New York: In connection with this rare form of eruption due to the ingestion of potassium iodid, I should like to call attention to another rare form, a case of which I recently presented before the New York Dermatological Society. The eruption was a very extensive one of the purely bullous type. When the patient, a colored girl of 12 years, came to the Vanderbilt Clinic, she presented a number of unpigmented circinate lesions that we were disposed to regard as dermatitis herpetiformis of the circinate and bullous type. The patient gave a history of having taken five weeks previously a bitter medicine in doses of ten drops three times a day for one week. At the suggestion of Dr. George T. Jackson she was given iodid of potash, ten drops three times a day. After the second dose an eruption consisting of large, tense, clear bullæ appeared on the whole body, more especially on the legs. Iodid was found in the contents of the bullæ and in the urine. The case is mentioned as an unusual form of an eruption produced by potassium iodid in an extremely susceptible patient.

Dr. F. C. Knowles, Philadelphia: In reference to the possibility of an eruption being produced by small doses of potassium iodid, I would refer to the case of Mackenzie, who described a case in an infant of five months where a small dose produced an eruption in 45 minutes, and the child died ten hours later.

DERMATITIS EXFOLIATIVA *

WILLIAM FRICK, A.M., M.D.
Professor of Dermatology, University of Kansas School of Medicine
KANSAS CITY, MO.

The name "dermatitis exfoliativa" may be given to any inflammatory disease of the skin which has for its most prominent features, inflammation and exfoliation of the epidermis. There may be features, however, histologic, etiologic or otherwise, which can be used to advantage in designating some of the types. Brocq recognizes seven types of exfoliative dermatitis. It may not be necessary to make as many distinct divisions as this, since several of these types may have the same or similar etiologic factors and differ only in degree of severity; still, we must acknowledge that there are as many clinical types as he describes.

The case I am about to report is evidently related to the more frequently seen cases of erythema scarlatiniform. Still I think that it would be a mistake to consider them identical.

The type known as "dermatitis exfoliativa neonatorum" or Ritter's disease, is a distinct type, and is generally conceded to be due to an infection at or near the time of birth.

The distinct type described by Hebra as "pityriasis rubra" is generally considered a fatal disease, but from time to time we have reports of recoveries of cases in all respects resembling this type, with the exception that they recover. There seems to me no adequate reason why they should be put in a different class. Frank Woodbury,[1] reports two cases, which he considers identical as examples of this disease. One of the patients died and the other recovered.

We have many other diseases which tend to a fatal termination in the severe cases, but in the milder cases of the same kind the patients recover. Why should we not consider this disease capable of the same variation and conclude that, while many patients die, others recover?

REPORT OF CASE

Patient.—B. K., a girl, 8½ years old at the time of first appearance of this skin disease, in April, 1907; her family history was negative. Her father, mother and two sisters are healthy. The cutaneous history of the family is negative. The patient had been healthy up to the time this disease made its appearance. Her skin was fair, hair inclined slightly to red, temperament nervous in mild degree, rather slender and of medium height for her age. She lived with her parents on a farm, where sanitary conditions are supposed to be good.

Present Illness.—The disease made its appearance as spots of reddened, rough skin, inclined to scale. These spots ranged from the size of a split pea to that of a silver dime; some were circular, while others were irregular in shape. The distribution was general over the body and extremities. At one or two places several of these lesions coalesced, forming irregular patches. Desquamation was in small scales. There must have been decided itching, as the parents say the child scratched until the blood flowed. Even while asleep, she scratched, which is indicative of severe itching. Her appetite was irregular and health not up to par. The parents of the child supposed this to be a case of multiple ringworm of the body, and it was treated as such. No physician was called at that time. In August, 1907, she had typhoid fever. This ran a reasonably mild course, the temperature at its highest being about 103 F. While the fever was present the skin disease disappeared completely, just as we see sometimes in psoriasis. When she recovered from the typhoid fever about September 15 the skin lesions returned, apparently about as they were before the typhoid made its appearance. They were the same red, slightly scaling spots as at first. The lesions were more numerous on the thighs than in other localities, but they were quite general in their distribution. This condition continued all through the winter, and in the spring of 1908 the family physician was called in to see the case. He considered it a case of disseminated ringworm and treated it accordingly for the next six months. There was no permanent improvement, but an increase in size of the lesions with more scale formation.

Examination.—When I first saw the case, Nov. 20, 1908, there were only a few of the smaller scale lesions present, and these were scattered about over the trunk and extremities without definite grouping. The larger ones had grown in size, ranging from 1½ to 3 inches in diameter, and were circular or oval in outline, not noticeably elevated above the surrounding skin, and had an erythematous base with thin papery scales covering the surface. At two or three places, several of these lesions had coalesced and formed irregular patches, but most of them were still discrete and were scattered promiscuously with the thickest distribution on the thighs. The distribution was about equal over the flexor and extensor surfaces. The lesions were sharply marginate.

Course of Disease.—My first impression was that I had an atypical psoriasis to deal with. An ointment was given, containing small quantities of salicylic acid and resorcin, in addition to internal treatment, and the patient was requested to return three weeks later. Promptly in three weeks the patient was brought to see me again. The change in these three weeks was great. Instead of scattering lesions, the entire skin was involved. I was informed that this involvement came, not by formation of new patches, but by extension of those present before. The whole process took on a more active appearance; the skin became brighter red and somewhat thickened. The process was extending up over the face and scalp, where it had not appeared before. The worst of the inflammation, however, all through the disease, was on the thighs and trunk. The face and scalp suffered least. This extension was accompanied by chilly sensations and fever. This began about December 1. The temperature was usually not high, but for the next two months it seemed to be always somewhat elevated, ranging from 99 to 103. There was no particular time for the increase in temperature, but the high points were just as likely to be in the early morning as late in the day. The discomfort of the patient, due to chilling, was quite marked, especially when circulating air came in contact with the denuded surfaces. Desquamation soon followed the extension of the inflammation. This desquamation left large patches of raw, oozing, sensitive skin. This was so general that the underclothes became at times saturated with the serous fluid. The patient did not complain of itching, but of a burning sensation, which she tried to relieve by rubbing. Desquamation occurred in small scales over the body and extremities. The palms and soles desquamated in large pieces. Toward the end of the disease the nails from the small toe on both feet desquamated also.. The other nails were rendered rough and ridged, but remained intact. The urine was examined at several different times and nothing abnormal was found. The heart, lungs, liver, spleen and all other abdominal and pelvic organs were normal as far as could be ascertained. No blood-count was made. The inflammatory process subsided gradually, the oozing grew less by degrees until it ceased altogether, the desquamation gradually disappeared along with the erythema and the skin became normal in appearance again. This point was reached about the end of April, 1909, about five and one-half months after I first saw the case. During the course of the disease the child had lost flesh until the bones became prominent. Now her appetite returned and the lost flesh was regained and more. A year from full recovery of this patient she remained perfectly well, has grown normally and has a skin as perfect as any child. In fact, there is no trace of the old trouble.

* Read in the Section on Dermatology of the American Medical Association, at the Sixty-first Annual Session, held at St. Louis, June, 1910.

[1] The Journal A. M. A., 1899, xii, 81.

Treatment.—This consisted, first, of the application of soothing applications to relieve the disagreeable sensations; oily preparations seemed quite effective and agreeable to the patient; second, of tonic remedies internally. Various tonic remedies were used, as seemed indicated. Along with this I tried the efficacy of quinin. I realized that this case was different from those in which Mook[2] seemed to secure so much benefit, but gave it a trial. The benefit received from this treatment was not great, but nevertheless the child's parents claimed some improvement from it. I could not say that treatment accomplished anything in a specific way; it merely supported the patient's strength and palliated the suffering, while Nature produced a cure.

I do not believe that the causative factor in all cases of this type is the same. As in scarlatiniform erythema, which it resembles, the causes may be various. In the case just reported I thought at first that the general inflammation might be due to the local application of resorcin or salicylic acid. It is true that these were applied in mild strength and would have required a skin with an idiosyncrasy to have produced the inflammation.

The involvement of the entire skin, even where none of the ointment was used, made it apparent that this was not the cause. Also we see that the inflammation continued and grew worse after the local applications were withdrawn. The continuation of the inflammatory process for three months before beginning to abate would indicate the continuation of the cause for that length of time. That this cause was a toxic agent generated within the body I believe to be the rational explanation of the trouble.

ABSTRACT OF DISCUSSION

Dr. Frank C. Knowles, Philadelphia: In the *Journal for Cutaneous Diseases* for January, 1910, Dr. John T. Bowen, of Boston, published a paper in which he described seven cases of dermatitis exfoliativa, five ending fatally. In a previous paper, presented to the American Dermatological Association in 1902, he divided these cases into four types.. The first was the recurrent desquamative scarlatiniform dermatitis; this form might occur after the ingestion of drugs. The second was the dermatitis exfoliativa of Wilson; the third occurred as a sequel to psoriasis, eczema, lichen planus, etc., and followed the administration of certain drugs, such as belladonna, mercury and quinin: and the fourth form was the pityriasis rubra of Hebra. I have seen a few cases of dermatitis exfoliativa, and recently, since the first of the year, I have seen a generalized case which followed the administration of quinin, and another in which the eruption appeared following the local use of a mercurial ointment. In this case the application was followed by an immediate generalized exfoliation of the skin.

THE NERVOUS UNFIT*

S. S. CROCKETT, M.D.
NASHVILLE, TENN.

It may have been the original intention of our Creator that all human creatures should start the race of life with the same equipment of physical and functional strength, and many generations back in the history of the human family such may have been the case. The profession would be relieved of an ever-present problem if all of God's favored creatures acted and reacted alike to the responsibilities of life, to the daily fight for bread, to the wild chase after wealth, to the exacting demands of social responsibility with all its joys and sorrows, with all its pleasures and disappointments, with all its cares and comforts, with all its successes and all its failures.

That so many fall short in being able to stand the tension of life's responsibility and fail to fill their measure of work at the end, is due to one of the following:

1. The development of some local or general diseased condition that puts an end to their existence.
2. Some diseased condition, local or general, resulting not in death, but in incapacity.
3. Incapacity without local disease being clinically present. The third class may be divided into (a) those overtaken by mental incapacity, and (b) incapables—mentally sound.

It is to the latter class that I beg to direct attention. The cases of this incapacity, in mentally sound persons, without any local pathologic condition being clinically present, may vary in shades all the way from those very slightly affected to the "ne'er-do-weel" or the chronic bedridden invalid who has long since abandoned all effort except that of complaint.

Some of these cases seem to be of congenital origin; consanguinity or inebriety of parents, or the presence in the parents of other neuroses or psychoses, having all been charged with causal responsibility.

Our social and educational systems are perhaps answerable for many of the cases of acquired incapacity. The more strenuous and exacting the occupation, the greater and the less interrupted the tension on the nervous energies, the more numerous the victims. The mad, merciless mania for money; the pitiless competition for preferment, that our neighbors may not appear better than ourselves; the great and criminal lack of individual attention to students in educational institutions; the too early exactions made of the nervous to the detriment of the physical side of the growing child; the unpardonable sin of our ever recurring written examination with all its attendant evils, and many more might be mentioned as causes of its acquisition. Neither age nor race, neither sex nor social condition seems to afford immunity.

The good housewife seems to be the sufferer in the greatest number of instances, and well may she plead justification. The continual grind of domestic routine, the determination of what to have to eat and how to have it prepared, three times a day, every day in the year, and then to begin all over again for another year, and for a whole lifetime; the ever-present servant problem, with its yearly increasing magnitude, the vigils of maternity, the education and clothing of children, the daily combat with the butcher, the baker, ice-man, laundry-man *et id omne genus*, each demanding a larger proportion of her allowance, not to mention the exactions of her social environment, constitute a draft on her nerve energy that would bankrupt any but an inexhaustible supply.

---

[2] Jour. Cutan. Dis., xxvi, 408.

* Read at the meeting of the Tennessee State Medical Association, at Memphis, April 13, 1910.

The financier who presides over the exchequer of a large enterprise, whose perplexing problems follow him home at night to disturb his domestic tranquillity and rob him of sleep, whose hasty meals are sandwiched in between the reading of the market quotations and telephone messages, etc., is often overtaken by an incapacity that seems unwarranted considering his age and apparent physical condition.

The minister, the ambitious student at college, the teacher, the professional man and especially the schoolgirl furnish large numbers of recruits to this ever-increasing army of incapables.

As paradoxical as it may seem, many cases are observed among the unfortunate unemployed children of wealth, who have never known the absorbing interest of earning their daily bread, who have so little to do that it is an effort to keep themselves physically fit, who are constantly begging for a potion for a night's sleep and who are strangers to that kind of slumber that has to be fought off till a task is done; whose organs of elimination from lack of physical activity are as foul as a surface sewer; whose digestive organs from early and long-continued over-indulgence have long since lost all that compensation that food brings to honest toil; whose principal occupation and whose greatest delight seems to be the contemplation of their own sensations. This class elicits our constant pity and commiseration.

These various groups of cases present a protean picture: Headache, backache, tender spine, tender nerve endings, gastric and intestinal disturbance, abdominal pain and tenderness, constipation, flatulency, occasional mucous diarrhea, disturbance and painful menstruation, palpitation, tachycardia, dyspnea, cold extremities, hyperesthetic and anesthetic areas, exaggerated reflexes, tire, inattention, inability to work, irritability, weakness, introspection, discouragement, hopelessness, chronic incapacity or invalidism—and all this while they are yet young and in apparently good physical condition.

The correct recognition and proper management of these cases is an ever-present and trying problem, and failure too often involves many fatal errors. The ready appreciation of the central origin of this incapacity is beset by two great stumbling-blocks:

1. These patients from constant introspection and analysis of their own symptoms assume to diagnose their own cases; it seems so simple; the stomach and intestines are upset and there is abdominal pain and tenderness, the trouble is abdominal; or there is constant pain in the back with menstrual disturbance; the trouble is located in the pelvis; or there is intermittent or constant headache that is made worse by much use of the eyes; hence there is certainly some error of vision; or perhaps there is tachycardia, palpitation and dyspnea, and heart disease is assumed. Having made a diagnosis, such patients at once elect to place themselves under the care of some professional man who devotes his activities to the treatment of the particular organ complained of, and then there develops the second stumbling block, which seems to have resulted from the following fact:

2. The limitation of our endeavors to any special line of professional activity seems to exaggerate and magnify that particular work in our minds until our perceptions are so restricted and our point of view so contracted that we are blind to all else, save those organs and tissues in which we are taking special interest. This seems to result from a one-sided development of our powers of observation, and is not limited to any special line of work.

Unhappily, the medical profession has not been able to rid itself of the mysticisms that still surround it in the eyes of the laity, and when a man makes a reputation on a certain line of work, the public assumes that he at once becomes an authority on all branches of the science—a pleasant misapprehension which is rarely corrected, but which is indulged in at times even by the man himself. Hence we see the doctor often falling into the same error as the patient and diagnosing disease in that complaining organ to which he is directing his special attention. That error is, however, as previously stated, not limited to any special line of work. These patients usually run the gamut of the profession and are successively fitted with beautiful glasses, have their stomachs washed out for a longer or shorter time, and then have a gastroenterostomy done; the appendix is next removed, and then are successively performed cholecystotomy, uterine and kidney suspension, perhaps removal of tubes and ovaries, dilatation or sewing up of cervix, removal of hemorrhoids, perhaps dilatation of an old stricture or massage of the seminal vesicles, and after all these procedures have been followed by brief improvement, temporarily justifying the idea that each succeeding new medical attendant has just really discovered the cause of all the suffering and is going to furnish the long-expected cure, the patient, if enough has been left to carry on his vital functions, then either becomes a victim of the infirmary habit, a chronic, neurotic incapable, or drifts into the ranks of some of dietetic or religious fanatics.

Is it not possible for us to draw a valuable lesson from our experience with these people? That the various diagnoses of so much local disease could not possibly be correct is beyond question; that improvement followed the treatment and assurance of relief in each instance may be true, yet a cure has not been effected. The hope and expectation of promised relief and the confident assurance of each and every new medical adviser that relief would follow each new treatment has conveyed to the confiding patient's mind the suggestion that that particular organ would be relieved, and it usually is for a longer or shorter interval. But is it not possible for us to approach the subject from a higher and broader point of view, and to secure more permanent relief?

1. It is essential to fix steadily before our own minds after thorough and painstaking examination the fact that the varied complaints of such patients cannot possibly be explained satisfactorily on the basis of local disease, but that they are probably due to a central cause acting through the nervous system, which, for want of a better name, might be designated "lack of nerve energy." Perfect frankness should be used in explaining to the patient that there is no disease present to account for the symptoms; that the complaints are due to a lack of nerve energy supplied to the tissues; that the tissues cannot discharge their functions without this nerve energy—that it is just as necessary to proper function as the circulation of the blood; that it is now proposed to institute a line of treatment that

will restore the proper amount and proper character of nerve energy; that restoration of function will result; that relief cannot come, however, without cooperation of the patient, in a new direction.

This explanation usually interests and seems to help the most fastidious and long-suffering. The greatest difficulty is experienced at the very outset, however, in convincing the patient, in the face of previous opinions, that there is no local disease present.

2. Restoration of function in any organ or tissue is impossible in the absence of the proper food-supply to that organ or tissue. Neurons and their multiple connections are no exception to this rule. An improvement in the food-supply of these patients is always of prime importance, and to accomplish this improvement is no easy task, as the belief in the presence of nervous indigestion has been indelibly impressed on the patients and they often consider themselves an authority on the subject of dietetics. Much help, however, may be derived from the constant suggestion that the trouble is entirely supradiaphragmatic and that the fear of food is unwarranted.

3. Chronic constipation is usually associated with the intestinal indigestion; mucous colitis is common, much abdominal pain and tenderness not infrequent, contributing an auto-infection from this canal that may not be an inconsiderable secondary etiologic factor; hence laxatives are continually called for, and may form a part of the daily regime.

4. Nothing is more important, impressive and suggestive than to have the doctor write out a program to occupy every hour of the patient's time, day and night, including amount, character and frequency of food, time, character and duration of baths, amount and time of isolated rest, hours in bed, amount of recreation and company, and an accurate instruction as to medicine, if any. In this way vicious habits of life may be corrected incidentally without friction, and the importance of the treatment impressed. Some of these patients are at times able to accomplish a considerable amount of work if their energies at other times are properly conserved. At times the only treatment that will be necessary at all will consist in temporary suspension of work, at other times change of occupation is the price of health and happiness.

5. In the effort to secure sleep many fall victims to drug addiction, an unfortunate complication always to be looked for, and a result to be carefully avoided. It will be difficult to avoid the occasional use of hypnotics; sleep, however, may be effectively secured by other and less dangerous means, to be mentioned later. The procuring of sleep by the regular use of narcotics is criminal.

6. The use of the cold bath in the treatment of these neurotic patients is an indispensible therapeutic agent; commence at first with a cold morning sponge, followed by a brisk rub, to be supplanted later by the cold spinal douche and then the cold plunge, effect is observed in procuring sleep, improved digestion, restored vascular, nutritional and metabolic equilibrium that is at times astonishing.

7. It becomes at once apparent, as already pointed out, that these patients are peculiarly susceptible to suggestion; otherwise the temporary improvement, under so many different lines of treatment, for different complaints, would not have been obtained. This temporary relief came from suggestion of relief directed to that individual complaint. Now with local disease out of the mind of the doctor and out of the mind of the patient, and the central idea of the trouble substituted therefor in the minds of both, is it not possible to substitute a conscious intentional and wholesale for the present unconscious and unintentional retail method of conveying the suggestion?

For the carrying out of this idea there are several prerequisites: the doctor himself must be of a tactful and magnetic disposition and possessed of a patience that would excite the envy of Job. The hearty cooperation of the members of the family is of importance; all of them are to be instructed to remark occasionally the patient's improved condition. Unkind criticism or reflection on former medical attendants is fatal to the effort. Patients must be prohibited from discussing their complaints with anybody but the doctor.

Electricity and vibration, aside from any inherent therapeutic merit, are perhaps the best vehicles in which to administer the suggestion. Either or both may be used alternately. A certain hour, on a certain day, must be selected and the engagement scrupulously observed. Negligence, indifference or inattention is at once followed by loss of cooperation. The patient's clothing should be removed and the surface of the body carefully gone over either with the electrode or the vibrator and as tender points are reached they should be gone over again carefully with the constant, confident, yet quiet assurance that the treatment will remove the tender spots. The greater the elaborateness, the more obscure the complexity of detail, the greater the amount of surface covered, the more forceful and lasting the suggestion. During the treatment and immediately thereafter the patient should be assured that it is always followed by more quiet and refreshing sleep, that digestion and appetite are constantly invigorated and the tender spots relieved, and that general comfort will follow until the next visit. On the next and all succeeding visits, before the patient has had an opportunity to begin the usual recital of discomforts, the doctor should be careful to remark casually on the improved appearance and better color, and at once to ask tactfully and carefully after each and all specific complaints, with the inquiry if they are not better. Optimistic suggestive inquiry, with confident reassurance, should characterize each and every interview.

I beg that this paper may be construed as a plea for a broader and deeper conception of the complaints of this class of patients, a conception which will carry the diagnostician beyond the consideration of local expression as an evidence of local disease, into the realm of mental control, where the seat of injury is often found in the loosening of that tie which should normally bind the higher subliminal self to functional activities.

Patients of this class are certainly entitled to every means of relief that can be afforded—dietetic, medical, surgical and hygienic; but shall we stop there, abandoning that wide field of psychotherapy, now holding such promise of development for the future?

All therapeutic measures belong to the medical profession, and failure on the part of the physician to add mental therapeutics to other treatment is, in my opinion, largely responsible for the ever-increasing numbers of devotees to those false religions whose tenets are neither scientific nor Christian, but who adroitly swell their ranks and promulgate their false doctrines by practice of this principle, so long well known, yet only recently being seriously put on a sane and healthy basis for the use of every practitioner.

PRESCRIBING OF LENSES FOR CLOSE WORK *

MARK D. STEVENSON, M.D., and E. M. WEAVER, M.D.
AKRON, OHIO

It will be possible to discuss only certain phases of this broad subject. Some procedures do not seem to be sufficiently well known, and require elucidation and emphasis in order to secure their more general adoption by those who prescribe lenses for the eyes. Before considering the prescribing of lenses for close work, the muscle conditions and static refraction for distance should be correctly determined. The latter is usually impossible without the proper use of cycloplegics, except in certain cases of myopia and in some people past middle life whose accommodation is weak or easily controlled. Sometimes the examiner must be satisfied with partial corrections, because fatigued yet determined, hypertrophied, habit-controlled, spasmodically contracting muscles are by no means limited to the young, but are often found in the eyes of the middle-aged with their more inelastic resisting lenses.

There are many young persons who suffer more or less distress, e. g., blurring, eye-ache and even headache after continued close work who experience no difficulty in the ordinary use of their eyes. In such cases it is a common custom to advise the constant use of lenses; during our first years in practice we made it a rule to do so. If there is no fixed vertical muscle imbalance, however, and no astigmatism or only a slight degree, less than .38 D., with weak spheres of nearly similar strength for each eye, the proper distant correction should be worn only for close work if all the symptoms are thereby relieved. In many patients it is more satisfactory to advise constant use of the lenses for the first few weeks or months until unnecessary ciliary contraction and consequent dimmed distant vision has more or less disappeared, when, if no symptoms remain, the patient may lay aside the lenses except for near work. Patients are often compelled by their advisor's orders to undergo the discomfort of constant use of lenses, although many, after a period of rest, disobey instructions, lay aside their lenses except for close work, discovering that they are comfortable without them. Such patients may lose confidence, and often go one step too far, discarding the lenses altogether for a variable time without discomfort, although possibly injuring the eyes by the added accommodative strain. It must be admitted that certain of these patients are not comfortable without constant use of lenses and it might be argued that in some the ametropia, e. g., astigmatism, is more likely to increase, but this chiefly depends on the individual and his work and can be known only by a fair trial. The oculist should not as a matter of routine advise such patients to wear lenses constantly. Of course, if there is considerable astigmatism or heterophoria present the patient may harm his eyes by not doing so and is not so likely to find comfort in their use for close work only. The eyes of the great majority of young people are hypermetropic, requiring the use of the ciliary muscles for clear distant vision, but such eyes, unless very hypermetropic, do not necessarily suffer distress or impairment of function in doing distant work; it is nearly always the added strain in near work that distresses and injures, especially if there is impairment of the general nervous system or the health.

The use of lenses in close work is often made necessary independent of the condition of the eyes for the distance. This is true when there is any impairment of the general health and vigor weakening the action of the ciliary muscle or influence of the third nerve, e. g., in conditions following various infectious fevers, especially after typhoid and diphtheria, and in certain toxemias and anemias as well as in cases of subnormal accommodation, or ciliary asthenia from other causes. In such cases pure hypermetropia of low degree might require lenses for only close work, while patients with considerable astigmatism or those who require prisms, especially one base up or down, usually should have bifocals. Lenses could be tried for near work, but, since these would not permit good distant vision, bifocals would be particularly helpful, especially in certain vocations, for instance, in that of a student. As the ciliary asthenia disappears the segments may be made weaker or dispensed with, leaving the proper distant lenses for distant and close work. In these cases there is a temptation to give too strong lenses for near work so as to help the patient as much as possible, but this discourages return of function in the weak muscle, although, according to Hess,[1] exercise can have no effect on the maximum of lens convexity. Duane[2] believes that exercise can increase the accommodation when weakened. Such patients should be requested to hold the reading, etc., as far away from the eyes as possible and to give the eyes frequent short rests from close work. Attention to general treatment and hygiene is very important, and posture, position, intensity of lights, etc., should not be neglected.

In myopia of about the same degree in each eye, over .50 D. and less than 2.00 D. or 3.00 D., and with little or no astigmatism, it is often best to have the patient wear the lenses only for the distance and lay them aside in close work unless he holds objects too close, necessitating too much strain on the muscles of convergence. In quite young persons it is better, if possible, to have the patients wear the lenses constantly in order to develop the accommodation. In myopia over 2.00 D. or 3.00 D. the use of bifocals is often advisable, great care being taken not to add too strong a segment. Space forbids a full discussion of anisometropia; but in cases in which a patient does not enjoy binocular vision or uses one eye for distant vision, the other for near, attempts to equalize them or adapt both to one distance will be fruitless and contrary to the best interests of the patient.

The far and near point giving a fair idea of the amplitude of accommodation should be found. In testing for close work, not only the best but also the nearest and farthest distances at which the print can be comfortably read with lenses should be determined. This gives the ordinary accommodative range. In difficult cases, especially in those who have previously complained of their lenses in close work, the accommodative range in each eye separately should be carefully ascertained. In testing the accommodation by means of test-types, the retinal image varies in size, depending on the distance of the test-type from the eyes. For accuracy this image should not vary in size and thus change the visual angle; therefore, ordinary tests with test-types or with lenses are inaccurate. I have found the punctumeter, a variety of Badal's optometer (Tscherning[3]) in which the retinal image remains the same size, convenient and sufficiently accurate, as by it the accommodation

---

may be quickly measured. Last year before this Section Duane[2] described a disc and method for testing the accommodation.

All these tests should be made with the patient's back to the source of light, thus avoiding contraction of the pupils sufficient to affect the result. Any of these tests may be misleading if the muscles have been fatigued by a previous long examination, especially if by fogging or other methods the patient has been induced to relax wholly or partially his accommodation. On the other hand, such tests made in the beginning of the examination, during or after it, when a spasmodic effort is made by the strained eyes of the anxious patient, may demonstrate greater accommodation than is ordinarily present. Accommodation in some people, especially in neurasthenics, in certain hysterical persons and in those with marked convergence defects, is very variable, the ciliary muscles easily becoming exhausted, so that it is instructive to make these tests early in the examination as well as after the eyes are tired. This exhaustion of the accommodative apparatus partially explains the blurring and other difficulties certain persons experience after continued close work which they do not notice in using the eyes for a short time. When the blurring begins they bring their close work nearer, securing magnification, sacrificing clearness but forcing additional work on their already exhausted ciliary and adducting muscles.

By the tests described above the amplitude of accommodation on the two sides may be shown to be quite unlike, the result of various diseases, especially those of the nervous system, usually weakening, paresis or paralysis of accommodation and possibly, in rare instances, spasm of accommodation. For close work it is occasionally necessary to place a stronger lens before the eye with the weaker accommodation. Commonly the difference between the lenses will be from one-third to two-thirds the difference of accommodation, or in young persons even less than one-third (Jackson[4]). It is very helpful to know that there is no accommodative power in some old people with not very clear media and small pupils. The vision may be so blurred that they cannot select the proper amount to add to their distance correction for near work, e. g., such a patient may not be able to chose between a +2.00 D.S. or +3.00 D.S. added to the distant correction. In these cases the equivalent in diopters should be added, as for 33 cm. a +3.00 D.S. should be added to the distant correction. While the range of vision with lenses for close work should be found in order to help determine the best lens, as too strong lenses often limit the range too much, and while the amplitude of accommodation should be determined and will prove helpful, rules for prescribing applicable to every case cannot be made. Probably no one could constantly employ his full accommodative power, but it is impossible to say whether a particular patient can use two-thirds or one-half of his power, as asserted by some writers. Some persons can use three-fourths of their accommodative power more constantly and easily than others can one-fourth. Fixed rules, a given distance or method are not applicable to all cases.

After having determined the ametropia for the distance, and, in special cases, the amplitude of accommodation, the distance which the patient prefers for close work should be ascertained. Next he should be placed with back to source of light and a test chart given to him. He should not be permitted to face the source of light, as this causes contraction of the pupils, partly preventing diffusion circles, thus doing away with the necessity for lenses and making it difficult or impossible to find the correct strength for ordinary conditions. The test-card should not be in direct sunlight, although it should be in good daylight without the patient's shadow on the card. Good artificial light from a source behind the patient serves well, and, as this is the kind of light commonly complained of, its use is often advantageous. He should be directed to look at test-letters of about the size of ordinary print, e. g., .75 D. or Jaeger 4. If the patient's vision is poor he should be directed to look at larger letters. If the test is made with very small letters the patient is likely to hold such letters a little closer than he would ordinary-sized letters, sacrificing ease and clearness to secure greater magnification. A sheet of ordinary music should be used when lenses are desired for reading music. If care is taken that the lenses are properly centered in the trial frame a seamstress may suggest something helpful as to distance if required to thread a needle and possibly to make a few stitches.

The range for the test-object should next be found; first, how far away the letters can be comfortably seen; next how close they can be easily read, and last the best distance at which they can be seen. The patient should be told to confine his attention to the distance for the lenses being tried, for if this distance is unsatisfactory it may be made right by other lenses and that, therefore, he should totally put aside his preconceived ideas of the proper distance for his work.

Persons in various vocations prefer different distances. A bookkeeper, type-setter, laundress, painter, carpenter, pianist, violinist or one who works at a flat-top desk rarely likes lenses which necessitate his coming close to his work, e. g., by leaning forward over books or desk. The lenses for the ordinary reading distance should first be found which will greatly aid in determining the proper lenses for particular distances. We have described our ideas about the proper distance for close work, especially as dictated by heterophoria and convergence tests, and the necessity for muscle exercises and prisms in these conditions in former papers.[5] These papers emphasized the point that, whenever lenses are prescribed, the intimate relation between accommodation and convergence is changed, requiring readjustment; further, that a patient with a strong desire for fusion, or single vision, may have marked ability to converge for a short time, or, for that matter, to rotate the eyes in any direction, just as a hypermetrope can accommodate, but that he is likely to become tired by such forced convergence, just as a hypermetrope becomes tired by forced accommodation, if the eyes must, in order to secure single vision, be rotated considerably from what may be termed their position of rest for any particular distance.

The examiner, in order to prevent early change of lenses and to thus lessen the patient's future expense, is often tempted to prescribe too strong lenses for close work. These limit the patient's range for near work, and, while lessening the accommodative stimulation to convergence, add to the convergence strain. For ordinary patients with good convergence power, for reading and sewing it is usually well to prescribe lenses for about 37 cm. This is a little too close for sewing on a machine or ironing, but is a good average distance. This distance is varied, depending on the vocation, desires of the individual patient, conditions of the extraocular muscles and convergence power and also dependent on whether there is binocular single vision. Unless the vocation demands otherwise, a one-eyed patient will usually prefer a strong lens if convex, and those with marked subnormal vision will also usually accept a strong lens, preferring magnification to clearness, range, etc.

---

[4] Jackson: Ann. Ophth., July, 1907.

[5] Stevenson, M. D.: Ophth. Rec., July, 1904, and February, 1907; Practical Importance of Hyperphoria in Prescribing Lenses for Use at Particular Distances and in Different Directions, THE JOURNAL A. M. A., July 17, 1909, liii, 203.

As in tests for the amplitude of accommodation, it is sometimes necessary to make separate and repeated tests for the best lens for close work, since the ciliary muscle, if exhausted by the previous examination, will require too strong a lens for ordinary use; that is, a lens which at the time of examination gives a reading distance of 37 cm. may in the ordinary condition of the eyes have a reading distance of considerably less. On the other hand, there might be a spasm of the ciliary muscle, and on continued use the lens would be too weak.

Accommodation is strongest in the young, not in infants, and gradually diminishes afterward until abolished. The age when special assistance to the eyes in close work because of weakened accommodation is first required varies, but much depends on the general health and vitality, the vocation of the patient, the amount and nature of ametropia or heterophoria present and the size of the pupils. Accommodation is the first important function to weaken and does so while the ordinary muscles of the body are growing and developing, possibly suggesting its biologically difficult and recent acquirement, especially as it is imperfectly developed in the savage and in the lower animals. In these times of overworked eyes, as in reading, embroidering, engraving, etc., special help for the accommodation is frequently demanded, i. e., a stronger lens if convex, weaker if concave, than the proper distance correction is required. Many patients over 30 or 35 complain of the use of their eyes only in close work. They are usually given their full or nearly full distant correction, to wear constantly. Many of these with a low degree of ametropia, especially with only a little astigmatism, with good extraocular muscles, will get greater relief and avoid the nuisance of wearing lenses constantly if a somewhat stronger convex or weaker concave lens than is required for the distance is prescribed for close work only.

Judgment and great care must be exercised in these cases. If there is much astigmatism or if a prism, especially a vertical prism, is required it may be better to prescribe only the full correction and as accommodation diminishes and this correction fails to satisfy in close work add a segment or give a separate stronger pair of lenses for near. A + .50 D. or + .75 D. segment added to the distant lenses often greatly aids the patient. It should not be forgotten that even if the ametropia for the distance is fully corrected in close work the ciliary muscle is compelled to make continuous effort, for instance, 3.00 D. at 33.3 cm. The time is probably coming when many more young people than at present will wear bifocal lenses, giving clear and easy vision at the distance and special aid in near work.

When patients past middle life complain only in doing close work and the eyes are normal or nearly so for the distance, lenses may be prescribed only for the former. In these cases, however, bifocals should often be prescribed, the patient being requested to wear them only for close work. Even a weak lens correcting the ametropia is preferable to a plane lens, and if a large segment with its upper edge just below the lower margin of the pupil is given in frames with good reading angle the patient will find it more convenient in doing his close work, not having to remove his lenses to see at the distance. The main objection to bifocals, viz., that the patient cannot see easily when walking about is removed, as the lenses are used only for close work. For patients who object to this use of a bifocal or for those whose vocation demands a whole lens, e. g., certain dentists or bookkeepers, a single lens is prescribed. Some prefer to use half or clerical-shaped lenses.

When there are symptoms of asthenopia, e. g., headaches, blepharitis, etc., due to a considerable degree of ametropia, two pairs or bifocals should be prescribed. Two pairs are better for those engaged in certain vocations, whose eyes must be directed through every part of the lens, as for dentists, bookkeepers, type-setters, sign-painters, etc., but they are inconvenient in many well-known ways. Two pairs require more care and must be frequently changed, especially difficult as it necessitates the use of both hands, a case, and some place to lay one pair of lenses.

To avoid the use of two pairs several substitutes have been used. Grab-fronts, whole or half lenses, grab-backs, whole or half lenses, are very serviceable in some cases. Half grab-backs serve like a bifocal both near and distant vision, but for those who wish a whole lens and desire to make quick changes the whole grab-back is useful. The grab-backs are not convenient for those who are often required to look upward, as salesmen in stores, painters or carpenters, for the grab-back then slips backward against the eyes; or for those who, like skirt-fitters, are often required to stoop, since the lenses are then liable to drop out from behind the spectacle frames. Grab-fronts hang on better than grab-backs, but are more difficult to adjust; and both are objectionable because of appearance, can be used only with spectacles, require careful and frequent adjustment and the rubbing together of the lenses scratches and mars their surfaces.

The most generally used substitute for two pairs is the bifocal, and, while the patient is usually disappointed in their use during the first few weeks, he usually likes them after becoming accustomed to the necessary blur of distant objects seen through the lower portion of the lens in looking downward and to the doubling of objects seen through the upper margin of the segment. The difficulty with this upper margin is much less in kryptoks and so-called invisible bifocals than in the older varieties. The patient should be given to understand that at first he must be patient with bifocals. In many ways they approach the ideal for two distances without any change of lenses. The segments are easily and cheaply changed. They may be prescribed either in spectacle or nose glass frames and with any degree of durability and elegance. For temporary use a detachable segment suggested by H. G. Huffman of Youngstown, in which the segments may be quickly clamped on the distant lenses by merely pressing them into a special case, may be employed. This form of bifocal may also prove useful in making a prolonged trial of double lenses. They are superior to other bifocals in that the patient may discard them when not doing close work, may have two pairs of them for different distances, may place one pair over regular bifocals and in that they can be easily decentered.

With bifocals the great difficulty complained of is in seeing downward at a distance—seeing the sidewalk, curb, etc., when walking. We formerly made the common error of trying partly to avoid this trouble by prescribing too small segments, by giving frames so that the segments were placed too far below the pupils. It did help the patient when walking about, but made near work more difficult and tiresome. The very small sizes require too much adjustment of objects looked at, give too small a field. Very large segments are required only for those who must move their eyes much in their work. They can scarcely be made large enough for bookkeepers and some dentists. Small segments for distant vision may be placed on the uppermost portion of the lens, the remaining large part being for close work. If the segment is placed too low the eye is compelled to look downward to such a degree as to tire the external ocular muscles. A false lens astigmatism is produced by looking through the strong segments at such an angle; also the effect of a stronger sphere results so that the patient is compelled to hold his work closer than was intended by the prescriber. This tires the eyes because of the increased amount of convergence required. Experience has taught us that the segment should be only very slightly below the pupil, especially in those who wear the bifocal only in close work, and that all lenses for near work, especially bifocals, should have the top tilted considerably farther away from the face than the bottom—a large reading angle.

Toric lenses give a better reading angle in the segment than ordinary lenses. With a good reading angle the eyes then look more directly through the lenses with less false lens astigmatism and with more nearly the spherical effect desired. Ordinarily the patient will soon accustom himself to walk about with segments high up. If spectacles are worn, for a time the frames can be pulled forward and down on the nose while the patient is walking. With nose-glasses, in close work, the reading angle should often be increased by tilting outward the top of the lenses. When a different prism is required in the reading lens from that in the distant lens it can be made in bifocals, but is often better employed in two pair. Last year before this Section one of us described a method by which hyperphoria in various planes for near work can be examined, and pointed out that, since it sometimes varies in different planes, it is necessary to prescribe different prisms for near than for the distance, also that such patients as well as anisometropic patients must learn how best to hold the head and eyes, that for such there is only one best position or plane in which the object should be held.

Everett Building.

ABSTRACT OF DISCUSSION

Dr. A. G. Bennett, Buffalo: I wish to take exception to one point in Dr. Stevenson's paper, and that is the statement that it is a waste of labor to try to make the patient with anisometropia use both eyes. I have had several instances of patients with one eye myopic and the other hyperopic or emmetropic using the emmetropic eye for distance and the myopic eye for reading. Some years ago I followed the advice now given by Dr. Stevenson and allowed the patient to use one eye for reading and the other for distance. But in the case of a young woman who came to me some years ago with a difference of 3D., I thought I would try to make her use both eyes. She had entire loss of accommodation in both eyes—the right eye from lack of use and the left eye *from myopia*, also from lack of use. So that she had a subnormal accommodation of at least 3D. I gave that patient a pair of hook-ons of 3D. to use before both eyes when reading or doing close work, with full correction for distance. Then I gave her some weak physostigmin (eserin) to use at night. She used the physostigmin and glasses three or four weeks. I was then able to reduce the hook-ons a half diopter. I continued that method of decreasing the strength of the hook-ons until in nine months she had full accommodative power. I have carried out this plan a good many times, and always with success, being able in every case to give them full accommodation.

Dr. A. E. Bulson, Jr., Fort Wayne: The accommodative power is influenced by so many factors that no hard and fast rules can be observed in the prescribing of lenses for close work. The health, temperament, vocation, habits, and the amount and kind of error of refraction may affect the muscular tone, and these factors may be inconstant. They must, however, be taken into consideration in the management of any case in which there is discomfort in using the eyes for close work. Some persons are thoroughly uncomfortable when wearing the full correction for close work, but derive the greatest benefit from a quarter, a half, or two-thirds of the correction. Other persons secure the greatest relief when wearing the full correction. A small percentage of patients will derive no lasting benefit from any correction, owing to inconstancy of muscular tone. Many cases, and the last class in particular, require treatment or a regulation of the habits or the conditions under which the eyes are used. I do not believe that in non-presbyopic cases we are ever justified in giving more than the full correction of the static refraction, for in such cases there is an urgent demand for a correction of the abnormality by means directed to the underlying cause. The lowered tone of the accommodative power requires something more than the effect of lenses, which do not aid in restoring the impaired function. The patients are generally, if not always, benefited by rest, coupled with whatever treatment may be indicated to aid in the restoration of normal accommodative function. The emmetropic eye should possess the necessary accommodative power for near work, as otherwise the eye is suffering from an impairment of function which calls for something more than lenses. The ametropic eye may possess all or more than emmetropic accommodative power, and the determination of the lenses required resolves itself into the question of an estimation of the amount of surplus accommodative power under average conditions, which, taken from the total refractive error, indicates with a fair degree of certainty the lenses which should be prescribed. Theoretically, a correction of the full amount of ametropia is indicated, but practically this does not work out satisfactorily in all cases. Here again we must take into consideration other factors which must be considered, not by correction with lenses, but by suitable treatment. We are also confronted with the effects of varying uses to which the eye is put. The person who works satisfactorily at one occupation with certain lenses may be very uncomfortable when the occupation changes. The person doing only an average amount of eye work very comfortably with a certain correction may be uncomfortable when doing something requiring more use of the accommodation. Therefore each case must be studied on its merits before it is altogether satisfactorily settled. The ophthalmologist who secures the best results will be the one who looks beyond the findings obtained from objective and subjective tests of the refraction before prescribing lenses.

Dr. Allen Greenwood, Boston: I want to emphasize what Dr. Bulson has said, that each case of refraction must be treated by itself. I also want to suggest a procedure which I have followed with great advantage, and that is, in young people who have a fair amount of esophoria, it is a good rule for a time to require glasses for near reading. The patient with exophoria very seldom will wear glasses for near. I also want to speak about anisometropia. I find that young people with the symptom uncorrected may be made absolutely comfortable with the proper correction for each eye.

Dr. S. L. Ledbetter, Birmingham, Ala.: Dr. Stevenson speaks of the difficulty in getting accustomed to bifocals on account of the blur that occurs in passing from the upper to the lower lens. There is a distinct blur, depending on the strength of the lower lens, for practically ⅛ inch in which nothing is seen. This is obviated by a little device which some of you may have heard of. It was suggested to me by a manufacturing optician. The usual bifocal segment is placed with the apex up. When the ray of light comes to pass through the segment it is deflected and gives more the appearance of coming from high up. Whereas, if you put the base up, when you reach the point of disappearance of the image, it produces a deflection so that the object is seen through the lower segment before distinct vision becomes lost through the upper, and you pass immediately from the upper to the lower segment, apparently seeing the object below before it has been lost from above. Mechanically, it does not look very bad, and it does away with the blurring. It can be made in the kryptok in the same way.

Dr. G. C. Savage, Nashville: There are two points not yet touched on in the discussion that are of vital importance. If you have cases of anisometropia, you can correct the error in each eye, but if you fail to tell the patients that they must look through the centers of the lenses, then they will get into trouble. To illustrate: Suppose I have a case of hyperopia of 2 D. in the right and 5 D. in the left eye. That is a difference of 3 D. Looking through the centers of the lenses there is no prismatic effect anywhere, but let the patient look one-fifth of an inch above the centers and he gets 3 degrees of prismatic effect vertically in the left eye; likewise, if he looks below one-fifth of an inch, he gets three degrees of prismatic effect vertically for that eye. The muscles cannot bear that sort of a displacement, and if the patient cannot look through the center of the lenses, he should be given the same strength lens as that given the better eye.

The other point is this: If you have a young person who has weak accommodation, it is the easiest sort of thing to tell it. You do not tell it in a haphazard sort of way; but place the patient behind the phorometer, and if he has orthophoria for distance and esophoria for near, that speaks for weakness of the ciliary muscles, and that weakness can be cured by gymnastic exercises. Instead of giving such a patient presbyopic lenses, I put him on exercise by means of concave spheres. I tell him what I want to accomplish. "The ciliary muscles require too much nerve force to do the focusing, and that produces a disposition to cross, and that gives a pull on the part of the externi to keep the eyes from crossing. You exercise these little focusing muscles as I tell you and thus will gain power and you will be relieved of the disposition to cross." When the concave spheres are put on, the patient should be 8 or 10 feet from the letter or figure on the wall to be looked at, and he should be told to raise and lower the concave lenses in front of his eyes rhythmically, like the tick of the old-time clock, at first for about two minutes, and add a half minute to each exercise until he gets up to ten minutes, and then for weeks or months exercise these ciliary muscles ten minutes just before retiring, so that the blood thus invited will build them up and make the muscles strong. These spheres should be —.75 D.

Dr. Joseph S. Lichtenberg, Kansas City: There is still one point that should be taken into consideration in fitting glasses for near, and that is the character of the light used. In our present-day civilization stenographers, bookkeepers and others are compelled to work by artificial light, principally incandescent electric or gas lights, and in this light there seems to be an irritant quality, possibly due to ultra-spectroscopic rays. My experience is that stronger glasses are necessary. Also under certain circumstances a certain tint can be given to the glasses, as amber, or amethyst tinted glasses, as suggested by Dr. Fox, or possibly those so-called ray filtering glasses, made by the German chemists.

Dr. Mark D. Stevenson, Akron, O.: Last year, before this section, I emphasized the importance of the anisometropic patient looking through the center of his lenses as much as possible; that he should turn the head, using the neck muscles instead of the external eye muscles, and that he should hold the reading matter as nearly on the proper plane—up or down—as he could. As stated, a full discussion of anisometropia was impossible in this paper. Usually the patient using one eye for distance the other for near, especially if there is a great difference between the strengths of the two eyes, will not appreciate attempts to equalize the eyes or adapt both to one distance. Of course, painstaking care and great patience on the part of both physician and patient will be occasionally rewarded by a brilliant result. As pointed out in the paper, I think the proper use of artificial illumination in testing for near work is very important, since it is commonly used by many patients. In asthenic conditions of the muscles the prime factor in treatment no doubt depends on the improvement of the local and general hygienic conditions and health—proper rest, exercise, etc.—but in many busy people there is a period before recovery when the eyes must be given more than ordinary assistance by lenses. This is not only demanded by the patient's necessity to use the eyes comfortably, but is often important temporarily in preventing harm to the eyes. As the whole is greater than the part, the examiner must not forget that he is above all else a physician, and that these cases require not merely local lens or other treatment, but, in addition and above all, his best skill in diagnosing and treating the underlying general cause or causes.

EDUCATIONAL WORK IN REDUCING INFANT MORTALITY

WILBUR C. PHILLIPS.
Secretary New York Milk Committee
NEW YORK

Step by step as we descend from the level of the extreme rich to that of the extreme poor, we find conditions increasing which militate against the lives of little ones. Where people are poorest, and where the scantiest means are found to combat evils which threaten, there invariably we find the darkest tenements, the narrowest and foulest streets, the lowest standards of living and the greatest ignorance. In consequence the death-rate among infants, as all persons know who work in these localities, is appalling. Especially in the summer, the babies literally die like flies. The fear of something terrible hangs like the sword of Damocles over the frightened, ignorant, and too often superstitious mother. Why does the baby die? The mother does not know. She knows only that her baby is vomiting and lying almost lifeless in their arms, and that at any moment it may follow where the others have gone. A timely word, telling her not to do the thing which makes her ignorance murderous, in many instances would save the baby. When the mothers begin to realize this their eagerness to learn, their hunger for instruction, is pitiful, more pitiful than physical hunger or its twin specter, undernourishment, stamped on the faces of so many, many women and children of our tenements.

This is the real tragedy of infant mortality—the unsatisfied desire of souls for knowledge, the permission of spiritual suffering and death.

To reduce infant mortality in its great and shocking totality, knowledge of infant-feeding, the hygiene of infants and all things pertaining to infancy must be placed first of all at the command of these poor mothers. The rich woman, the middle class woman, must also be taken into consideration, but the long red columns of infant deaths will not begin to shrink until the campaign deals effectively with those whose lack of knowledge is most pitiful and distressing.

Last year in Greater New York 15,977 infants less than 1 year of age died from causes which were largely preventable. No figures exist to show what percentage of these deaths occurred among the rich, middle class and poor respectively, but it is safe to say that a large majority, probably four-fifths, occurred among the people of the tenements. Some basis for this claim may be obtained from an investigation of Health Department records made by the New York Milk Committee in January, 1908. Three sections of the city were included—one section of twenty-eight blocks, comprising a fashionable residential district in the neighborhood of Fifth Avenue, Madison Avenue and Central Park; the second of five blocks comprising a middle-class residential district in the neighborhood of One Hundred and Thirty-fourth Street and Lenox Avenue; a third of three densely populated blocks comprising a typical tenement-house district bounded by Avenue A, East Seventy-fourth Street, First Avenue and East Seventy-second Street. In 1907 the estimated population of the three districts and the number of births recorded were as follows:

	Population.	Number of births recorded in 1907.
28 fashionable blocks............	7,561	37, or ½ per cent.
5 middle-class blocks...........	7,696	160, or 2 per cent.
3 tenement blocks...............	7,858	434, or 5½ per cent.

Thus we see that in the above areas containing approximately the same population, three times as many babies were reported born to poorer classes as to the middle classes and eleven times as many to the poorer classes as to the upper classes. These figures are undoubtedly influenced considerably by the fact that most wealthy women and many women of the middle classes, go out of the city for confinement or are confined in institutions not included in the districts above named.

A fair estimate of the ratio of births among the three classes would probably correspond with the figures for Paris, Berlin, Vienna and London, reported by Dr. Bertillion at the Congress of the International Statistical Institute of St. Petersburg in 1887, which are as follows:

PARIS

If the birth-rate of *rich* = 1, then *middle* = 1.5 and *poor* = 2.3

BERLIN

If the birth-rate of *rich* = 1, then *middle* = 1.9 and *poor* = 2.6

VIENNA

If the birth-rate of *rich* = 1, then *middle* = 1.7 and *poor* = 2.0

LONDON

If the birth-rate of *poor* = 1, then *middle* = 1.4 and *rich* = 1.9

It is safe to say that in the districts above mentionel, twice as many babies were born to the poorer classes as to the middle classes and four times as many to the poorer classes as to the upper classes. These figures, although not so sensational as the actual comparative birth-rates reported to the Health Department, nevertheless show a striking contrast.

Knowing that the greatest danger to infants exists at the time of greatest heat, the Milk Committee, at the suggestion of Dr. L. Emmett Holt, selected a period of fourteen days, of which the first seven comprised the hottest week of 1907. In this way not only the immediate but the after-effects of a period of excessive heat were observed—something that is rarely done. The average mean temperature of the first week from July 18 to July 24 was 78.6 degrees and of the second week from July 25 to July 31, 76.4 degrees. In the three tenement-house blocks sixteen deaths, or 4 per cent. of the total number of infants known to have been born during the year died during the two weeks—nine during the first week and seven during the second. Had a similar death-rate prevailed throughout the rest of the year the mortality would have been 100 per cent. In the four middle class blocks and in the twenty-eight wealthy residential blocks of approximately the same population no deaths were recorded.

These facts tell their own story. The probable absence for the summer of most of the wealthy mothers and many of the middle-class mothers cannot be considered, as the ability to leave a hot city and thus avoid a principal cause of infant death—like the ability to employ infant specialists, trained nurses, etc.—is a purely economic advantage. Light, air, sanitary surroundings and proper nourishment, are all factors in the reduction of infant mortality. The lack of the means to purchase these commodities spells misery, disability and death.

VALUE AND KINDS OF INSTRUCTION

Because of the facts already mentioned, instruction and educational work, up to the present time, has been largely confined to mothers in the lower strata of society. This educational work has been of three kinds: (1) home instruction by nurses; (2) class instruction by doctors; (3) combined class and home instruction by doctors and nurses.

1. *Home Instruction by Nurses.*—The first educational campaign of house-to-house visiting in New York City was started by the New York Association for Improving the Condition of the Poor in the summer of 1907, when a small army of nurses, with headquarters at Junior Sea Breeze Hospital, were detailed to work in the Nineteenth ward, bounded by Thirty-ninth and Ninetieth streets between Fifth Avenue and the East River. These nurses visited mothers in their homes, instructed them in the care and feeding of their infants, and, as often as was necessary, revisited them and gave additional advice.

As a result of this work (for other reasons seem to be lacking), the deaths among children in the Nineteenth ward in 1907 was 222 against 254 in 1906, although the death-rate among infants and young children from diarrheal diseases throughout the summer was higher for the entire city in 1907 than in 1906.

Stimulated by the excellent results of this work, the New York Health Department in the summer of 1908 detailed a force of 83 nurses to do instructional work in the five boroughs in Greater New York. Each borough was divided into districts which were in charge of a chief medical inspector and a supervising nurse. Instruction was confined to the mothers of new-born babies whose births were reported to the Health Department. On being notified of these births the nurses visited the homes and, if the case was not already in the hands of the family physician or some competent person, instructed the mother, and, by follow-up visits, saw that the baby improved in health.

In this work the Health Department cooperated with the Conference on the Summer Care of Babies (now called the Conference on the Care of Babies, as it is intended, under the newly created Bureau of Child Hygiene, to continue this work throughout the year), an organization composed of representatives of some fifty societies and agencies directly or indirectly interested in the problem of infancy and motherhood. As the result of the combined and coordinated efforts of the Health Department and these agencies the mortality-rate among infants under one year of age was lowered in Greater New York from 17,438 in 1907 to 16,230 in 1908, and to 15,977 in 1909. In the summer of 1909, 140 nurses were detailed to this work by the Health Department alone.

2. *Class Instruction by Doctors.*—The idea of educating mothers in consultation or classes was first conceived by Dr. Budin in the Tarnier Clinic in Paris. Dr. Budin observed that many mothers, after leaving his maternity hospital, returned in two or three weeks without their babies. On inquiry, he found that these little ones, who had been dismissed in good health, had died; and he finally came to the conclusion that their deaths occurred largely because their mothers had no idea how to feed and care for them. As a result of this discovery,

Dr. Budin organized groups or classes of mothers, who had been delivered at the hospital, and who, after dismissal, returned to him at regular intervals, bringing their babies to be examined and weighed, while they themselves received oral instruction in infant-feeding, infants' hygiene and other matters affecting their little ones. In this way began the great movement of the *consultations de nourrissons*, which has since spread throughout Europe and was introduced in America in 1908 in the infants' milk depots maintained by the New York Milk Committee at that time organized under the New York Association for Improving the Condition of the Poor.

In the French consultations as well as in the consultations connected with the committee's depots the main thing striven for was the encouragement of breast feeding, an educational feature of great importance. No nurses were employed in the French consultations, concerning which Dr. Budin made the statement that the main essentials were a pair of scales and the service of a devoted physician.[1]

3. *Combined Class and Home Instruction by Doctors and Nurses.*—Believing that educational work among mothers would be greatly strengthened if connected with the distribution of pure modified milk, (a conclusion reached in France where, it was discovered, the *consultations de nourrissons attained their greatest efficiency* when connected with *gouttes de lait*) the New York Milk Committee on June 15, 1908, opened seven infants' milk depots in congested districts of Manhattan. In these depots pure milk was distributed to infants under the supervision of trained nurses. Volunteer physicians examine the babies weekly, weigh them, prescribe their food and talk to the mothers on infant hygiene in very much the same manner as do the physicians in the French *consultations de nourrissons*. The French method has been improved on, however, by the addition of the trained nurse who, by her home visiting and by her personal contact with the mothers, not only greatly enhances and strengthens the work of the physicians, but in many cases, where other demands intrude themselves on the doctor's time, actually bears the main burden of the educational work. In these cases the doctor prescribes and attends to the feeding, and the nurse instructs.

In order to compare the value of group educational work in milk depots, with that of group educational work independently organized, the committee supported two nurses who were in no way connected with the distribution of milk. These nurses cooperated with physicians, and organized consultations or classes at which feeding and hygienic instructions were given. From the results of this work[2] it was apparent that combining the instructional work for mothers with the distribution of milk greatly enhanced its efficiency and effectiveness, as the necessity of securing milk from a certain depot not only attracts mothers to it in the first place, but, by bringing them, either directly or indirectly, in daily contact with those who prescribe the milk, at the time when they obtain their supply, maintains a steady interest on their part which otherwise might be sporadic, easily interrupted and discontinued on slight excuse. Because of the continuity of this work as well as because careful records are kept of the weight and physical condition of the child when received; of the period of observation; of the regularity of attendance; of the continuity of physical progress while under observation; and of the weight and physical condition of the child when dismissed, the results of this work are both definite and trustworthy.

In the seven depots maintained since June, 1908, 1,207 babies were regularly (that is, for periods of three months or more) under supervision of the physicians and trained nurses. Careful records were kept of 466 cases; these records show that 55 per cent. of the babies were rated as fair, poor, bad or moribund; 70 per cent. of the families lived on $5 to $15 a week; 64 per cent. were housed in one, two or three rooms; 85 per cent. lived under conditions that were below normal; 64 per cent. of the mothers were rated as ignorant.

In spite of these facts, which it may be assumed apply to the entire group of infants fed by the Milk Committee, *the average gain in the physical vitality of the depot babies as estimated by the Bureau of Sociological Research was 24.6 per cent. and the number in good condition grew during the year from 45 per cent. to 78 per cent.*

Owing to the limited time and effort of the nurses, control was not exercised among many babies who might otherwise have been saved. Of those under control, eleven or less than 2 per cent. died.

This record of a work which is not yet perfected, demonstrates conclusively that by educating prospective mothers and by throwing about them all possible social safeguards, it is certain that a large number of deaths which now occur from ante-natal causes can also be prevented.

Educational Work of the Future.—In considering the future of educational work for mothers, it is important to remember that the quantitative problem of reducing the sum-total of infant mortality by carrying education to the mothers of the poor is no more important, although perhaps more striking and gratifying in its apparant gross results, than the qualitative problem of saving the lives of children, better fitted by heredity and environment to supply vigor and stamina to the nation.

Inasmuch as knowledge, that is to say, education, is a commodity, like milk or sugar, to be purchased or given away, those mothers who desire and can pay for instruction should be able to purchase it, while those who equally desire, but cannot afford to pay for it, should obtain it free. In this connection, the idea has long been in my mind of commercializing the work of supervision and instruction, which is now carried on by the Milk Committee's physicians and nurses in the tenement districts of Manhattan, just as the committee is actually commercializing the sale of milk in its depots. Indeed, many persons hold the opinion and often express it, that the time will come when physicians—and what applies to them applies equally to the nurses—will be paid to keep people from being sick and not to cure them when they are well. People able to pay for the knowledge which will accomplish this result would, in this case, be made to pay for it, and people handicapped by poverty, sickness or disability would be allowed to obtain it at part price or for nothing at all. The doctor who could duplicate on a paying basis among the upper classes what is already being done gratuitously among the poor with a sufficient variation of method to meet the altered demands of his patients, in the opinion of some persons, would be surprised by the success of his undertaking. The work might be extended to include the period of pregnancy, the importance of which is felt by all persons working on the subject of infancy. This would be a practical way of educating the middle class and wealthy mother, requiring only the energy and initiation of the practitioner, assisted as he is at present in other matters, by a trained nurse.

---

[1] The results of the work started by Dr. Budin and carried on in France have been summarized in a Plan for Reducing Infant Mortality in New York City, which I published in the Medical Record, May 30, 1908. *Detailed information concerning the consultations held in connection* with the Milk Committee's depots will be found in the committee's report entitled Infants' Milk Depots and Their Relation to Infant Mortality. Copies of these publications can be obtained by writing to the New York Milk Committee, 105 East Twenty-second street. An article descriptive of the method of conducting a consultation, written by Dr. Ira S. Wile, who has charge of the Milk Committee's depot in Bloomingdale Guild, 146 West One Hundredth street, appeared in the May number of the Dietetic and Hygienic Journal.

[2] Infants' Milk Depots and Their Relation to Infant Mortality, p. 59 of the Milk Committee's report.

For the mothers of the poor, free municipal education, the foundations of which have already been laid by the New York Health Department, must inevitably be extended. While ignorance as gross as that found among the foreign inhabitants of our overcrowded communities continues to exist, infants' milk depots, because of the natural and tangible hold exercised by them over poor mothers, will prove a valuable aid.

As the problem of the baby's health is largely a feeding problem the proximity to the milk-supply of those who prescribe the food and give the instruction is an important consideration. It is to be hoped that the time will come when milk satisfying the requirements of physicians can be secured at a reasonable cost by all mothers who have need of it; but the value of merely referring such mothers to places where they can get milk will be increased if by daily supervision over them as they come for it, those upsets and irregularities, so often fatal, are immediately attended to. Keeping one's eye on a large group of infants in widely separated homes is a difficult matter. The nurse who sits in a milk depot and receives daily the reports brought from her little patients by those who must come for the baby's daily supply is much better able to feel the pulse of her situation and intelligently to direct her energies than the nurse whose only knowledge is obtained by a separate visit to each infant. When education and social reform have eliminated bottle-feeding, by securing mothers who can suckle at the breast, the milk depot, with its abnormal features, will not be needed. The high mortality among bottle-fed infants urges a campaign of instruction and enlightenment which will accomplish this end.

By carrying to all mothers, then, rich as well as poor, the knowledge how to feed and care for their infants—having the mother at the same time under the supervision of a physician assisted by a trained nurse, who, either on a charitable or commercial basis, supervises the child's feeding and by home visitations and demonstrations, emphasizes the educational features of the work—the problem of infant mortality will solve itself. Eventually, in one form or another, this is what it will come to—mothers will either demand and receive instruction for which they will pay, or will so sorely need it that others, in pity, will supply it free. Whether there is need of coordinating this work of paid or professional instruction with free or municipal instruction is not clear. Here, as in all other educational problems, public and private education will follow the usual lines—education for the many falling more and more into the hands of society as a whole, that is to say, in the hands of the state or municipality, and education for the few confining itself to smaller and more expensive groups.

WANTED—EDUCATORS FOR INFANT WORK

In all this educational work one need of paramount importance has received practically no attention up to the present time. This is the necessity, if we are to educate, of securing properly qualified instructors for our infant work. It is not enough for a few doctors to have carefully studied the infant and its needs. Knowledge on these matters should be more generally extended to all physicians, for however greatly the general health of the community may be elevated and sickness correspondingly decreased, as long as the world lasts, women will become mothers, children will be born, and inexperience and ignorance must be replaced by intelligence and foresight. It will not be enough, if the work is to be educational, preventive, that the doctors know simply the technical side of their problem; they must be instructors, too, able to teach others what they know, and if they labor with the poor, as some of them will, they must also have some idea of those social problems which are not learned in the laboratory and the lecture hall. Consultations may be established, schools for mothers may be founded, instructional work of one kind or another may be ever so carefully conceived and organized, but all, like a boat without oars or a college without professors, will be of no avail unless there are trained instructors to do the work.

The need of educators for infants' work has been particularly emphasized in the work of the New York Milk Committee where few of the nurses and physicians feel fully qualified for the work. It is one thing to feed and care for; another thing to instruct and prevent. Examining and prescribing are matters of individual attention; teaching can also be done individually but experience has demonstrated that the collective or group method is best. And not all doctors are qualified for this class-room work.

What can be done by group instruction, in which emphasis is placed mainly on prevention by education rather than on scientific feeding alone, has been demonstrated by Dr. Ira S. Wile at the committee's milk depot in Bloomingdale Guild, 146 West One Hundredth street. Dr. Wile talks to about thirty mothers of various nationalities at his weekly meeting. As each baby is weighed and examined he comments on its condition, either praising the mother for the manner in which she has followed his instructions or criticizing her for indifference or neglect. These remarks are accompanied by advice and instruction suggested by such incidents or circumstances as may happen to arise, as, for instance, the need of household as well as personal cleanliness, suggested by a dirty baby; the danger of overdressing, suggested by the long red flannel bandages enveloping an Italian baby; the value of breast-feeding, suggested by remarkable gains in weight of a child recently taken off the bottle; the danger of crackers, sugar, beer, tea, etc., suggested by the anemic condition of a child fed on those articles. This information delivered week after week in an entertaining way has wrought a great change not only on the mothers themselves but on the whole character of the neighborhood in which Dr. Wile has worked. Of course not all of the mothers listen all the time, any more than a college student pays precisely the same attention to every word that falls from the mouth of his professor. The total effect of the work, however, is of great value and shows what can be done by a real teacher in work of this description.

Dr. Wile educates at the same time that he feeds, using each mother, baby and incident in the life of each, as an illustration to his text. This method has been criticized because many physicians feel that their work is of an individual nature and that best results are obtained when they deal with their patients privately. This is undoubtedly true if they are prescribing for patients. It is not true if they are educating to prevent sickness, for that is work of a different nature—educational work to which educational methods must be applied. All persons realize the value of personal, intimate relation between doctors and patients, but after the examination and prescription (if it is quite impossible to do two things at the same time), should come the lesson which teaches and prevents. If the doctor can feed at one time and educate at another, well and good. If he *can* only feed and not educate, an educator must be secured in addition.

It is because doctors are not educators that this important work is often left to nurses who work under them. Possibly there is a reason for this; possibly women are naturally better fitted to teach other women than are men. I will not say that this is not so (and certainly if it is so, it opens up a new and attractive educational field to women), but the need of physician educators must nevertheless be met. At present these educators *do not* exist. Physical directors tell us how to care for ourselves but the physician has contented himself mainly with administering pills and medicine to us when we are sick. This the future will surely alter. Prevention by legislation, and social reform are not enough. There must be prevention by education, carried to the masses by the newspapers and magazines and to individuals directly by men and women who employ known methods of educational work. The problem of infant mortality is in its infancy. Taking life at its source, it lays the foundation for all future health and physical efficiency. The doctor who can teach and prevent is the one needed. If there are no educators they must be manufactured; if in no other way by establishing schools of medical and physical pedagogy. For the doctor is the educator of the future; the best knowledge is that which gives life, and gives it most abundantly.

THE PRESENT STATUS OF THE ETIOLOGY OF SQUINT *

WILLIAM ZENTMAYER, M.D.
PHILADELPHIA

Twenty-five years ago, the theory of Donders as to the causation of squint seemed firmly established despite the objections brought forward at that time by Schweigger, but since then several new theories have been advanced, one of which at least, has secured a considerable following. A study of the various monographs bringing forward theories other than the accommodative one shows that there is a lack of unanimity regarding the essential phenomena entering into the question. Thus one observer (Straub[1]), who believes that a failure of the development of binocular vision accounts for both the hyperopia and the squint, admits the almost constant and important association of the two conditions but has not found that the vision in the amblyopic eye can be improved frequently or materially by practice, and in those instances where parallelism of the visual axes is obtained he finds that only the rudiments of binocular vision have been secured.

Worth[2], the introducer of the theory of the failure of development of the so-called fusion faculty, does not find that there is an undue proportion of hyperopes of moderate degrees among squinters, but he does find that by practice the vision of the amblyopic eye may usually and greatly be improved and binocular vision established.

Bjerke[3] states his belief that a peculiar innervation is the cause of squint, finds in the refractive error *only* a favoring influence and claims that the amblyopia is primarily a cerebral suppression and for a long time only functional, or we could not have the enormous improvement in vision which follows exercise of this eye. He also finds that binocular vision is so frequently recovered after operation for squint that it could not have been primarily undeveloped and thus the cause of the squint; and he says, further, that many can squint who have excellent binocular vision. The declination and hypertropia theory is brought forward by its sponsor (Stevens[4]) because he found these conditions almost constantly associated with squint and because he found *no relation between* hyperopia and convergent strabismus.

An analysis of the assertions contained in the above summary shows such contradictions in the findings and in the results of treatment that it would seem that they must result either from bias or from conclusions drawn from too few observations. One author finds constant association of hyperopia and convergent squint; another finds no such association; one finds that the vision in the amblyopic eye cannot often or materially be improved; another finds that not only can vision be improved but that binocular vision can be established by practice; one finds that when binocular vision is secured it is only *rudimentary* while another finds it so *frequently restored* after operation that he is convinced that the center for binocular vision could not have been undeveloped.

According to its opponents, the inherent weakness in the accommodative theory is that it is not always high-degree hyperopes who have a convergent squint and that not all squinters are hyperopic.

The fact that some clinicians have not found a greater relative proportion of hyperopia and convergent squint than would be accounted for by actual greater frequency of this refractive condition of the eye, has caused these observers either to discard Donders' theory or to assign but a secondary importance to the refractive error.

Stevens, who believes the causes of convergent strabismus to be the declination of the meridians of the eye and hyperphoria (the latter usually itself the effect of the declination), gives the state of the refraction in 67 of his cases of esotropia. Of this number 23 individuals were emmetropes, 18 myopes and 20 hyperopes. The estimations were made without the use of cycloplegics. He has observed that "in many cases in which during the period of life while accommodation was active, atropin revealed a supposed 'latent hypermetropia,' there has been no indication of hypermetropia when, as the result of presbyopia, years later, the accommodation has been practically abolished." He says that "it thus appears that the mydriatic may cause a condition of apparent hypermetropia, which is not the normal refractive condition of the eye."

He justly holds that the figures given above do *not* sustain the view that convergent strabismus is caused principally by hyperopia but then these figures are at variance with those of all other writers. I do not share in the opinion expressed by Stevens regarding the production of hyperopia by the use of a mydriatic. I have oftener seen a hyperopia develop or an existing hyperopia increase at the time of life when the accommodation is weakened by age. More rarely, a decided rapid increase in the refraction of the eye is seen as the result of swelling of the lens at this same period of life.

[4] Motor Apparatus of the Eye, Philadelphia.

I have made a tabulation of 485 cases of convergent strabismus with hyperopia in groups according to the refractive error present in the meridian of lowest error of the fixing eye. This plan was followed in order that the results might be compared with the statistics of Worth which are similarly arranged. In my series, all the estimations were made under cycloplegia produced by a 1 per cent. solution of atropin instilled into the eyes three times daily for from 2 to 5 days. Reference to the table published by Worth will show that in 66 per cent. of his cases the hyperopia was over 3 D. In my series this group represented 44 per cent. of the whole. In 68 per cent. of Worth's cases the error was higher than 2 D. In mine in 70 per cent. Basing the calculation on the highest meridian of the deviating eye my series shows that in 55 per cent. the error was over 3 D, and in 75 per cent. it was over 2 D. It will be noted that in 10 per cent. the error was over 6 D.

TABLE 1.—FOUR HUNDRED AND EIGHTY CASES OF MONOLATERAL CONVERGENT SQUINT ARRANGED IN GROUPS

Refractive error in the lowest meridian in the fixing eye.	No. of Cases.	Percentage Whole Numbers.		Refractive error in the highest meridian in the deviating eye.	No. of Cases.	Percentage Whole Numbers.
Not above + 1 D	48	10	56%	45%	33	7
Above + 1 D, not above + 2 D	98	20			86	18
Above + 2 D, not above + 3 D	126	26			96	20
Above + 3 D, not above + 4 D	90	19	44%	55%	102	21
Above + 4 D, not above + 5 D	55	11			76	16
Above + 5 D, not above + 6 D	36	8			43	9
Above + 6 D, not above + 7 D	20	4			31	6
Above + 7 D, not above + 8 D	5	1			12	3
Above + 8 D, not above + 9 D	3	0.6			3	0.6
Above + 9 D, not above + 10 D	...	..			3	0.6

Comparing the above percentages with those in a series of 250 cases of hyperopia without squint, grouped according to the refractive error in the highest meridian, in which the patient sought relief from asthenopia, it was found that in only 10 per cent. was the error over 3 D, and in 27 per cent. over 2 D, and in only 1.2 per cent. was the error above 6 D. There were no cases in which the hyperopia equalled 8 D. In a series of 500 cases in which the percentages are calculated on the error in the lowest meridian of either eye it was found that in less than 5 per cent. was the error above 3 D, and in 16 per cent. above 2 D, and in less than 0.5 per cent. was it above 5 D. In the above 2 series the estimations were made either under atropin or homatropin cycloplegia.

TABLE 2.—TWO HUNDRED AND FIFTY CASES OF HYPEROPIC REFRACTION ARRANGED ACCORDING TO THE REFRACTIVE ERROR IN THE HIGHEST MERIDIAN

	Number of Cases.	Percentage Whole Number.	
Not above 1 D	50	20	92%
Above 1 D, not above 2 D	137	54	
Above 2 D, not above 3 D	46	18	
Above 3 D, not above 4 D	11	4	
Above 4 D, not above 5 D	9	3	
Above 5 D, not above 6 D	4	1.6	
Above 6 D, not above 7 D	1	0.4	
Above 7 D, not above 8 D	2	0.8	

TABLE 3.—FIVE HUNDRED CASES OF HYPEROPIC REFRACTION ARRANGED IN GROUPS ACCORDING TO THE REFRACTIVE ERROR IN THE LOWEST MERIDIAN

	Number of Cases.	Percentage Whole Number.	
Not above 1 D	270	54	96%
Above 1 D, not above 2 D	150	30	
Above 2 D, not above 3 D	61	12	
Above 3 D, not above 4 D	9	2	
Above 4 D, not above 5 D	8	2	
Above 5 D, not above 6 D	1	0.2	
Above 6 D, not above 7 D	1	0.2	

Some years ago I tabulated for Dr. William F. Norris 378 cases of convergent squint in reference to the state of the refraction. In 96.4 per cent. there was hyperopia, in 1 per cent. there was anisometropia and in 2.9 per cent. there was myopia. A consideration of the above figures will show that not only is hyperopia the preponderating refractive error with other refractive states in a negligible quantity but that in considerable more than one-half of the cases, when the estimation is based on the highest meridian of the deviating eye, the hyperopia is above 3 D, and slightly less when it is based on the lowest meridian of the fixing eye. They also show that the high errors are of far more frequent occurrence than in non-squinting eyes, outnumbering them 10 to 1[5].

In the presence of a hyperopic error any condition which would reduce the vision of one eye below that of its fellow would act as an exciting factor in the production of a convergent stabismus, and this factor is frequently found in the existence of a higher degree of hyperopia or an astigmatism of a higher degree in one eye than in the other or in an unilateral astigmatism, as shown in the Table 4.

TABLE 4.—TABLE OF COMPARISON OF THE REFRACTIVE ERROR IN THE TWO EYES OF SQUINTERS

	Percentage.
Astigmatism greater in the deviating eye 0.50—1 D	17
Astigmatism greater in deviating eye over 1 D	25
Astigmatism greater in fixing eye	12
Hyperopia greater in deviating eye, 0.50—1 D	10
Hyperopia greater in deviating eye over 1 D	20
Hyperopia greater in fixing eye	2
No difference	10

According to my figures, there is not the close correspondence between the number of hyperopes of over 2 D in squinting and non-squinting patients, found by some clinicians.

Worth admits that hyperopia stands in some close etiologic relation to convergent strabismus, but considers that a defect of the so-called fusion faculty is the cause of the squint. If a defect in the fusion faculty be the cause why is this defect so largely associated with hyperopia of middle and high degrees and not oftener with hyperopia of low degree, emmetropia and non-progressive myopia? In my series, only 30 per cent. of patients had hyperopia of less than 2 D, whereas in hyperopia without squint this amount of error represented 72 per cent.

A fusion faculty which had normally developed up to the time of the occurrence of a squint from disturb-

---

5. In tabulating the cases which were obtained from the records of Dr. Norris, it was remarked that in the earlier years when less exact methods of determining the refractive error were in use the estimations gave a lower degree of hyperopia than in those obtained from more recent records and this probably accounts for the lower percentage of higher degrees of hyperopia in my series than in Worth's.

ance of the normal relations between accommodation and convergence might lose its function when the need for such had disappeared with the loss of binocular vision. A similar loss of function is seen in the amblyopia of an eye which has been turned. In children convalescing from febrile disorders, and particularly from whooping cough, the power of accommodation is weakened and if the child returns to its books during this period a convergent strabismus sometimes results even though there may be present only a low or moderate hyperopic error. The weakening of the accommodation produces a disturbance of its relation to convergence precisely in the same manner as does a higher degree of hyperopia with a normal accommodative power, and a squint results even at an age when the fusion faculty is believed to be fully developed. The fact that patients with convergent strabismus have been cured by developing the fusion faculty after the method of Worth is taken as proof that a defect in this faculty must have been the cause of the squint. However, the method by which the cure of the squint is brought about consists of many steps and this renders it difficult to decide in what degree any or all are concerned in bringing about the result. The first step is the correction of the existing refractive error. The second is the overcoming of the amblyopia in the turned eye. The third is developing true fusion. The fourth is increasing the amplitude of fusion, during which procedure the angle of the tubes of the amblyoscope is altered in a way that aids in a restoration of the parallelism of the visual axes. The fifth is the further development of the fusion faculty by stimulating it to bring about binocular vision with the sense of perspective under equalized illumination of the objects.

Every clinician has observed how frequently the simple correction of the refraction error relieves the squint, and there is general agreement that Worth's ingenious method of restoring vision in the amblyopic eye is productive of excellent results; furthermore, in increasing the amplitude of fusion something is also accomplished in the way of diminishing convergence excess. So that aside from its purpose in developing the fusion faculty, the treatment must aid materially in restoring the normal relations between convergence and accommodation.

One of the cases reported by Worth is of particular interest. It was that of a child 5 months old with H.—5.5 D in one eye, and 6 D in the other. This child was cured by glasses and an occlusion bandage. Worth's explanation is that by giving glasses and so relieving strain on accommodation the visual axes were in the course of from 5 to 6 weeks brought back to parallelism and this allowed the natural development of the fusion sense to take place.

If it be as Worth says that the fusion faculty was allowed to develop naturally by reason of the visual axes having been brought back to parallelism it follows that if the visual axes had not been brought back to parallelism the fusion sense would not have developed naturally; and this, it seems to me, explains why the fusion faculty is found undeveloped in those cases of squint in which the refractive error has not been early corrected and in consequence of which a convergent squint has occurred. In other words, the undeveloped fusion faculty is a result and not the cause of the squint. The theory of the absence of a normally developed fusion faculty seems best adapted to explain essential alternating squint; that is, a squint which does not evolve into the monocular permanent type but which continues through life as an alternating one, as here, as a rule, the visual acuity and the refraction are not at fault. To me, it would seem that these facts, the absence of an error of refraction and the equal visual acuity of the two eyes, which sustain the theory when it is applied to this class of strabismus, rather weakens the theory when it is sought therewith to explain permanent monocular squint, as this form is so constantly associated with hyperopia and unequal vision (which determines the deviating eye that later becomes amblyopic). It would seem reasonable to suppose that the almost constant feature is the essential causative one.

The perfect correlation of the facts in myopia with divergent strabismus, with those in hyperopia with convergent starbismus, is a strong argument in support of Donders' theory. As the divergence does not occur early in life, but appears only after the developing myopia has produced a derangement of the normal relations which exist between convergence and accommodation, the fusion faculty is found to be well-developed. Notwithstanding this, it is powerless to maintain the parallelism of the visual axes when once the coordination between these faculties has been disturbed.

The theory of Donders is upheld by the following facts: Convergent strabismus is associated with hyperopia in over 95 per cent. of the cases; the average degree of refractive error is very much higher in a series of cases of hyperopia with convergent stabismus than it is in a series of cases of hyperopia without squint; there is usually a difference in the refractive error in the two eyes sufficient to unequalize the visual acuity and thus favor a deviation of the more defective eye; in a considerable number of cases the correction of the refractive error relieves the squint (I believe that this number would be greatly increased if glasses were prescribed as early as the third year of life. Worth has shown that it is perfectly possible for them to be worn at an even earlier age); the fact pointed out by Donders that a convergent squint can be produced by placing before the eye a concave glass; that divergent strabismus is usually associated with myopia and that the same process of reasoning by which it is shown that hyperopia is the cause of convergent stabismus serves to explain the causation of divergent strabismus by myopia.

It appears to me that when one approaches the subject with an unbiased mind and considers the facts as they are, the accommodative theory accords best with these facts and when it fails in individual cases these can well be explained by other known causes of strabismus, such as congenital palsies, structural defects or anomalies, favoring effects of abnormal orbital axes, divergence weakness and congenital amblyopia. I believe, with some other authors, that congenital palsies of the ocular muscles are more common than heretofore supposed and that some of the cases of monocular permanent squint apparently comitant, with normal vision in the squinting eye, are the end results of paralytic strabismus.

I wish to express my thanks to Dr. J. Hiland Dewey and to Dr. D. Forest Harbridge for their kind assistance in the preparation of the statistics of this paper.

1819 Spruce Street.

ABSTRACT OF DISCUSSION

DR. CASSIUS D. WESCOTT, *Chicago:* One of my revered teachers was fond of saying that "no effect is the result of a single cause." It is quite likely that there are two or more causes, each *one* evinced, in every case of squint. The multiplicity of opinions held to-day as to the cause of squint would, of itself, indicate the probability of a *variety* of causes of this defect. It must be true, however, as Dr. Zentmayer suggests, that some who have written on the subject "have been influenced by bias, or have drawn their conclusions from the study of too few cases;" or, I would add, from a faulty method of study. I think we need not, for example, long consider the opinion of one who studies squint cases without a cycloplegic or who finds 23 emmetropes in 67 cases studied. Mr. Worth's contribution is important, if true, but I cannot avoid the feeling that his studies have been made to establish a theory rather than for the purpose of learning all of the truth about squint. He gets rather careless of his theory, however, when he tells about the little girl of 5 months, referred to by Dr. Zentmayer, cured by glasses "which restored parallelism and allowed the natural development of the fusion sense to take place."

My own experience would indicate that convergence excess induced by excessive accommodation due to hyperopia is a sufficient cause of convergent squint in a very large number of cases. If, added to this, we have defective vision, or more complicated refraction in one eye, we have another potent reason for squint. Dr. Zentmayer's figures are very suggestive in this connection, and he has placed us all under obligations to him for presenting his tables, and bringing this subject before us once more. I believe with him and Dr. Duane that the undeveloped fusion faculty is often a result of squint; that it is ever the sole cause, I very much doubt. We must not forget the anatomic conditions which favor squint. Dr. Risley especially has called our attention to the formation of the head, and the direction of the axes of the orbits in connection with both dynamic and static squint. In accounting for some cases of squint, as well as for the fact that not all hyperopes squint, it is well to remember also the very great individual difference in the elasticity, or amplitude of the relation between accommodation and convergence. It is also quite possible, as Dr. Duane says, that convergence excess with divergence deficiency, and the contrary conditions, are due to central causes. I see no reason why any case of comitant convergent squint should not be alternating, provided vision is equally good, and the refractive error relatively the same in both eyes. The thing that determines constant squint is the low vision, or more difficult vision of one eye. I do not mean to undervalue the labors of Mr. Worth or the assistance he has given us in the treatment of this troublesome condition, but I quite agree with Dr. Zentmayer that the results of Worth's treatment do not prove the correctness of his premises as to the etiology of squint.

Dr. G. C. Savage, Nashville, Tenn.: Dr. Zentmayer has presented about the sanest paper on squint that I have ever heard in this Section. The fundamental, underlying essential of binocular single vision is corresponding retinal points. Without this there can be no such vision. I am going to show the fundamental underlying principle of corresponding retinal points, and that its non-existence is the cause of that form of squint which no man has ever yet corrected or ever will correct. At the crossing of the vertical and horizontal meridians is the macula of each eye. Now they should correspond one with the other. Let us begin at the macula on the right side and follow a fiber to the commissure, across the commissure and on until it terminates in a cell of the left cuneus. Then let us trace a fiber from the left macula until it terminates in the same cell of the left cuneus. A double image means a double impression. The double impression carried along these two nerve-fibers to a single cell means a single sensation, and therefore means that the images have been fused. Unless common brain-cell connection exists there is no such thing as binocular single vision. Now, tracing the fibers to separate cells in the same cuneus, or finding that one macula is connected with one cuneus and the other with the opposite cuneus, would mean double sensation and impossible fusion. Corresponding retinal points mean common brain-cell connection. In the absence of common brain-cell connection there can be no fusion. Now we know that we have a case of squint depending on want of common brain-cell connection because of two things: first, the child squints at birth and squints from that time on; second, whether in a child or a youth or an adult or an old person, one eye sees as well as other alone. That I call insuperable squint. You may try to fuse these images only to fail. They will cross or recede. You may get these close together but they will not fuse, because of the want of common brain-cell connection. But suppose you have a case of squint that has occurred in the second or third year. You will find that at the time of crossing or squint the vision in the crossing eye is low. In a few years it is less still, and still lower later on, and finally there is no vision in the squinting eye at all. This is the kind of a case in which there is a common brain-cell connection; but because of the existence of factors that lead to divergence, convergence, elevation or depression, one image must be suppressed by the mind, and the mind begins to suppress it, and keeps on suppressing it until the power is perfected. We can train the blind eye out of its blindness after operating. These are the cases I like to find for the patients can be cured.

The fusion power is a power of the mind. There are fusion centers and over these fusion centers the fusion faculty of the mind presides. Each fusion-center has its own muscle under control, and only one muscle. Now suppose a child is born with common brain-cell connections and there is a disposition for the development of squint. If the eye turns in or out far enough to let the image go beyond the fusion retinal area the eye will stay turned until properly treated. As long as may be possible the fourth basal centers, by acting on the two externi, will prevent the interni from crossing the eyes, but these centers act only when the images are on the fusion area, and thus under the stimulus of the fusion faculty of the mind.

Dr. L. Emerson, Orange, N. J.: It does not seem to me that there is opportunity for controversy between the theories of Worth and of Donders on the etiology of squint. I am very much a believer in Worth's theory. There is without question a fusion faculty, and a point which Worth makes and which does not seem to be clearly understood is that there may not only be an absence of the fusion faculty, but a deficiency thereof. Now as underlying all cases of squint I have never seen one case in which the fusion faculty was not either deficient or absent. There is also the cause, hyperopia, and given these two things, absence or deficiency of the fusion faculty and the presence of a refractive error, you can account for nearly all forms of convergent squint. The deficiency of the fusion sense explains why we have cases of squint in which there are no refractive errors, and there are many of these cases of squint which can be cured by proper methods. The patient has a perfect cure and yet with the stereoscope or amblyoscope it is absolutely impossible to get any fusion up to the second or third grade, showing that there is a deficiency of the fusion sense.

Dr. W. Zentmayer, Philadelphia: I have no quarrel with Worth as to the existence of a fusion faculty. I do not doubt that it exists, and I do believe that its absence may be the cause of certain cases of convergent squint.

THE NORMAL VARIATION OF THE SYSTOLIC BLOOD-PRESSURE

A STUDY OF ONE THOUSAND CASES

H. P. WOLEY, M.D.
CHICAGO

The practice of taking blood-pressures in insurance examinations has become comparatively common in the last few years. The question was soon asked, What is the normal blood-pressure? Is the blood-pressure different at different ages and, if so, what is the difference? We all know that the pulse may fluctuate between certain limits, say 60 to 85, and still we would not hesitate to say that a person within those limits was in health. If it is beyond either limit we would make a further study of the case, fearing that it might be a pathologic condition.

The medical examiner, from an insurance standpoint, is in the opposite position from the general practitioner in his office, for the latter is dealing almost entirely with cases in a pathologic condition, while the insurance medical examiner is dealing with healthy persons and trying to find out how far their cases may deviate from the normal, typical case and still be healthy and a first-class risk. He is trying to establish boundary lines, a high mark and a low mark, within which an applicant may be safely considered in health, and outside of which he would be looked on with suspicion.

With these ideas in view I have collected, during the past three years, the records of 1,000 blood-pressures, all of supposedly healthy individuals. There has been excluded every case of kidney disease, heart disease, and in fact, every case in which there was a pathologic condition found, either from physical examination or from the history. These cases represent typical healthy individuals, ranging in age from 15 to 65. These records were all taken by five different physicians. Often they were taken by two physicians working together. Again, records were made at the same sitting with two different instruments: for instance the mercury column and the Collins or the Dr. Rogers' Tycos sphygmomanometer. From time to time the instruments were corrected or standardized by subjecting them to the same pressure and then the readings taken. This was done by using the usual 5-inch cuff, but one having several openings or rubber tubes, to each of which a sphygmomanometer was attached. When the pressure was raised in the rubber bag, an equal pressure was made at the same time on every instrument. This was done to reduce the liability of error and insure as far as possible an accurate and uniform reading. All of the results herein recorded were made by using the 5-inch cuff about the arm, with the subject in the sitting posture, and the systolic reading taken at the point at which the pulse disappeared and reappeared, with the finger on the radial artery.

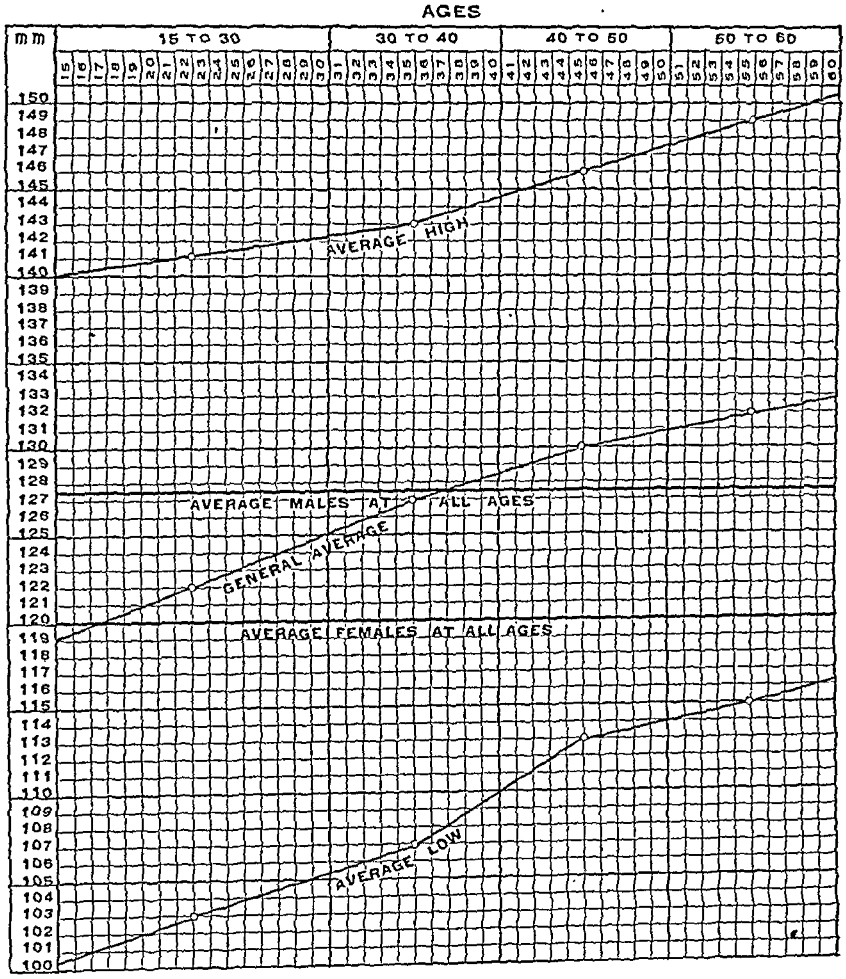

Chart showing the normal limits of variation in systolic blood-pressure.

From comparison and study of many cases during the last five years, I believe that, at any age, a constant blood-pressure of 160 mm. or over is pathologic, and therefore should be excluded from forming any part in the results or conclusions reached in this paper. Many of these cases have been studied, where it was possible, and albumin and casts have been found in the urine sooner or later, though sometimes in small amounts. It explained the condition, however. This has been of considerable assistance, for many risks might have been accepted as first-class, were it not for the abnormal elevation in blood-pressure, which led to a further study.

Experience has taught us that the selection of a single individual's blood-pressure, as a high mark or a low mark, would be manifestly unreliable, while it is equally certain that the general average of a group of blood-pressures would be pretty nearly the truth. The larger the group the more accurate the results. It is found to be practically correct in considering vast numbers of supposedly healthy individuals that about 85 per cent. prove to be healthy and 15 per cent. are questionable. Following this principle, I shall take the general average of the group of 15 per cent. of the highest blood-pressures and the general average of the group of 15 per cent. of the lowest blood-pressures, and designate them as the average high and the average low blood-pressure.

With this explanation, the results reached after a study of 1,000 blood-pressures are as follows:

The average blood-pressure for males at all ages was 127.5 mm.

The average blood-pressure, for females, at all ages, was 120 mm.

By taking them in groups, first, from ages 15 to 30, the average blood-pressure was 122 mm. An average high blood-pressure of 141 mm., and an average low of 103 mm.

Second, those from 30 to 40 years of age gave an average blood-pressure of 127 mm. An average high of 143 mm., and an average low of 107 mm.

Third, those from 40 to 50 years of age gave an average blood-pressure of 130 mm., an average high of 146 mm., and an average low of 113 mm.

Fourth, those from 50 to 60 years of age gave an average blood-pressure of 132 mm., an average high of 149 mm., an average low of 115 mm. These are best shown by the accompanying chart.

By looking at the chart it will be noticed that the maximum and minimum blood-pressures are about equally apart from the average blood-pressure at a given age. It can also be seen at a glance what the average blood-pressure with its maximum and minimum marks should be at any given age from 15 to 60. There is a gradual rise in the blood-pressure as the years advance. There is also a corresponding rise in the high and low averages. It can be readily seen that between 50 and 60 years of age a man giving a blood-pressure of 145 mm. could undoubtedly be accepted without further question, while a man under 30 years of age giving the same blood-pressure would present a case for further study and investigation.

In regard to women, it will be noticed that the average blood-pressure at all ages was 120 mm., about 8 mm. below the average in males at all ages. There is practically the same ratio of increase in blood-pressure in women as in men at the same age. In women it averages 8 points below the men.

It is a source of regret that the number of cases above the age of 60 proved to be too small to obtain a fair average. There appeared, however, to be quite an advance in blood-pressure above the age of 55. Therefore, I have selected the group from 55 to 65, which gives an average blood-pressure of 138 mm., an average high of 153 mm., and an average low of 120 mm.

There are a few points worthy of notice that might be mentioned here, namely, in regard to the pulse—rapid or slow. The average blood-pressure in all cases with a pulse under 65 was 123 mm., while the average blood-pressure in all cases with the pulse over 85 was 130 mm. It was also noticed that there were twice as many healthy individuals with a pulse over 85 as there were with a pulse under 65.

It was the desire in making the above study to obtain as far as possible the normal variation in blood-pressure in health, which would be of practical service, not only to the insurance examiner, but to the general practitioner. It would not have been sufficient to accept the blood-pressure alone; therefore, physical examination of every case was necessary in order to exclude all of those who were in any way impaired, thus leaving, as far as it was possible, typically healthy individuals.

THE ADVANCEMENT OPERATION IN SQUINT *

VARD H. HULEN, A.M., M.D.
HOUSTON, TEXAS

Teachers of ophthalmic surgery have long advocated the more frequent performance of advancing and shortening operations, and some do them exclusively in preference to tenotomy for strabismus, but I believe that most of us are still very largely doing tenotomies. It must be that none of the various methods of advancement are considered entirely satisfactory, the simpler operation of tenotomy being more frequently chosen, hoping thereby to obtain an acceptable result.

Most ophthalmologists will agree that the advancement operation is more certainly corrective, physiologically more scientific, and functionally safer than tenotomy, and it is my conviction that a tenotomy alone should rarely be done in any case of squint.

A rather extensive observation of the work of various operators, including repeated visits to many of the large European eye clinics, convinces me that the ideal advancement operation has not yet been presented. There are certain requisites for this ideal operation, as they appeal to me:

First, the method must be simple and expeditious in order that the average patient may submit to it under local anesthesia and that the average operator may use it satisfactorily.

Second, when the operation is done under general anesthesia the determining sutures should be under such subsequent control that any possible deviation may be easily corrected when the true position of the eyes is ascertained.

Third, the scleral suture should not depend in the least on the episcleral or conjunctival tissues for its support.

Fourth, one suture firmly introduced into the sclera is sufficient and it should be placed with the tendon insertion in view and before the muscle has been severed.

Fifth, the suture in the tendon must be firmly lodged to avoid a tendency to give or cut out, yet it must not be looped or knotted to the muscle, which would impede the vascular supply of the tissues involved and also make its removal difficult, thereby endangering the satisfactory adhesion of the tendon to the sclera in its new position.

Sixth, and this is very important, the tendon and globe should not be pulled into the position for fixing by the process of tying the sutures.

An old surgical law, the observance of which is particularly important in ophthalmic surgery, which forbids that tissues be pulled into position by the sutures, is broken in nearly all the methods for advancement known to me. Traction aids will eliminate the operator's agony from broken sutures or cut and strangulated tissues due to vain efforts to obtain the desired position by straining at knots already tight.

Apropos of these statements I beg to describe an advancing and shortening operation which I first did five years ago and which, with slight modifications, has since seemed to have fulfiled my requirements. Reference to the two accompanying diagrammatic illustrations will render a minute description unnecessary. Figure 1 shows the method of introducing the sutures; Figure 2 shows the position of the traction sutures in use and the method of knotting the fixing sutures.

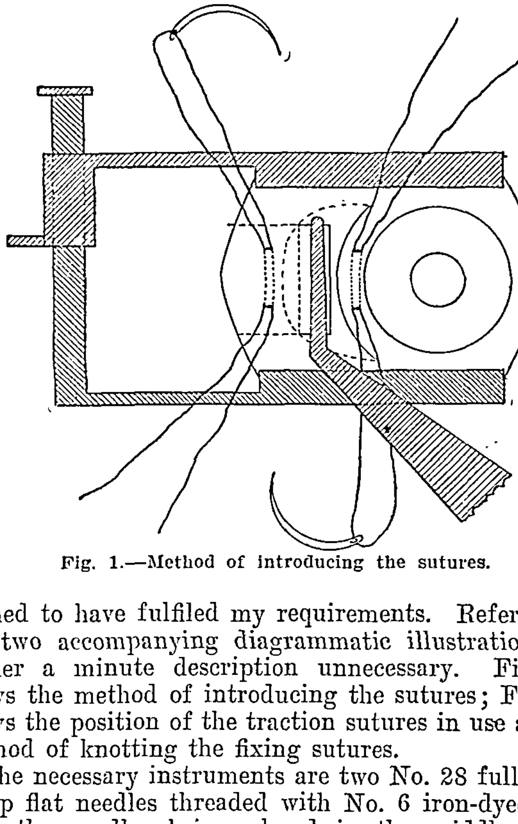

Fig. 1.—Method of introducing the sutures.

The necessary instruments are two No. 28 full-curved sharp flat needles threaded with No. 6 iron-dyed black silk, the needles being placed in the middle of the sutures, a needle holder, fixation forceps, a strong pair of advancement or muscle forceps, tenotomy scissors, and a speculum; a strabismus hook is often useful.

The procedures are the same for either the internal or external rectus. After complete anesthesia, local or general as the case may require, the speculum is introduced, the conjunctiva pinched up and incised vertically about 4 mm. from the cornea; the incision is extended above and below parallel with and corresponding to about one-third the circumference of the cornea, and the conjunctiva separated toward the cornea and the site of the tendon. Next the tendon is loosened along its upper and lower margins and clamped close to the scleral insertion with the muscle forceps, including the

---

* Read in the Section on Ophthalmology of the American Medical Association, at the Sixty-first Annual Session, held at St. Louis, June, 1910.

distal margin of the retracted conjunctival wound. The globe is held in perfect control with the muscle forceps, and, the tendon insertion being completely exposed, the scleral stitch should be accurately placed. The conjunctiva is first entered from without inward, then with the needle firmly grasped in the holder the suture is inserted vertically into the sclera close to the limbus, taking as deep and wide a bite as is safe, and the double suture drawn half-way through, again penetrating the conjunctival flap.

The tendon is next severed from its attachment, all the tissues as held in the jaws of the forceps are lifted and stretched into position for placing the second suture; the needle is made to penetrate from without inward through conjunctiva, Tenon's capsule and muscle at a point one-fourth the width of the muscle from one edge and as far back as we may wish to advance, the doubled suture is pulled half-way through and the needle is reintroduced at the corresponding point from the other border penetrating, from within outward, muscle, check ligament and conjunctiva.

The muscle forceps are then cut loose by severing the tissues as far from the jaws as one wishes to shorten, but not close enough to the suture to weaken its hold.

The needles are removed by cutting the sutures close to them. It will then be seen that there are really two sutures in the sclera and also two in the muscular tissues. One of the scleral sutures and one of the muscle sutures are crossed and used during the tying part of the operation for traction purposes only. The assistant has perfect control of the globe and the muscle by means of these traction sutures, and when he has brought them into the exact position required for correct fixation the operator ties loosely with a double twist the upper ends of the other sutures, the lower ends of those sutures are similarly tied, then he tightens the upper knot, now the lower one, and so on until the proper tension has been secured; each knot is then completed by the final twist, and the operation is practically finished. Supplementary conjunctival sutures will rarely be required.

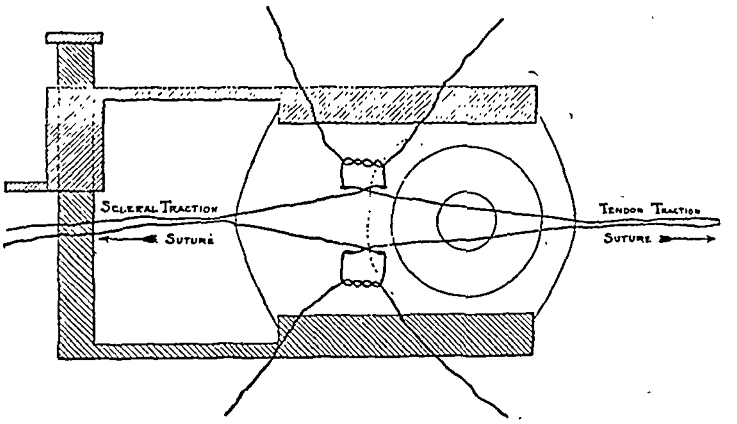

Fig. 2.—Position of the traction sutures in use, and the method of knotting the fixing sutures.

Many details and important points not here described will readily occur to the surgeon performing this operation, or are common to all similar procedures.

Under general anesthesia, we cannot be sure of the correction, and it is one of the decided advantages of this method that the sutures used for traction can be left *in situ* until consciousness is regained. I usually allow them to remain until the following day, and if the squint has been materially over-corrected the tied sutures are removed, and the traction sutures are used to fix the eye in its correct position with but little discomfort to the patient or embarrassment to the operator.

At the conclusion of the operation done under local anesthesia we can be satisfied to remove the traction sutures immediately.

Also, should the surgeon prefer in any case to do the "tucking operation," the method should be precisely the same as described, except that the tendon is not severed, the muscle forceps are simply unclamped (the scleral suture will have been placed further from the limbus) then, when the traction sutures are used the muscle is smoothly folded on itself and any desired tension or position fixed by knotting the other sutures as in the strictly advancing operation.

Both eyes are bandaged and the patient is kept quiet. In five or six days the sutures are removed by cutting the upper one to the nasal side of the knot and the lower suture to the temporal side of its knot, or *vice versa*, and lifting them out.

It might be added that in doing this operation under general anesthesia, especially in marked squint, in which I combine it with tenotomy of the opposing muscle, a control suture is introduced through the tenotomized muscle and its stump.

In this method of advancing an ocular muscle attention is directed particularly to its simplicity, to the minimum amount of traumatism to all tissues, to the accuracy possible and security obtainable from the method of anchoring the scleral suture, the vertical introduction is decidedly advantageous, to the efficient "bite" of the tendon suture looped across the under surface of the muscle, to the perfect control of the parts to be united by means of the traction sutures which were obtained without additional suturing, and to the advantage of having already at hand a perfectly placed pair of sutures to be used, if required, for correcting any over-effect following the primary operation.

Scanlan Building.

ABSTRACT OF DISCUSSION

Dr. H. H. Briggs, Asheville, N. C.: The great variety of principles and methods employed in shortening an ocular muscle is sufficient evidence that no one method satisfies even the majority of ophthalmic surgeons, or is adequate for the correction of the various types and degrees of heterotropias with which the clinician is constantly confronted. Were there one and only one exact and best method of changing the anatomical relationship, and therefore the physiological effect, of an abnormally acting muscle, surely some one of our confrères of to-day, not to mention the great ophthalmologists who have gone before, would have discovered it. Even as it is, we have graduated tenotomists, partial tenotomists, tendon stretchers and tendon tuckers. If no operation for advancement had ever been made, and if one familiar with the anatomy and physiology of the eye, and surgical technic, should be required to devise a method of advancing or shortening an ocular muscle for the correction of heterotropia, I fancy he would reason thus:

1. It must be done without danger to the vision and with the least possible chance of infection. In these days of aseptic surgery we expect healing without infection, but in wounds made in mucous membranes we can never be absolutely sure of this, and to this end the amount of suture material and the number of knots should be reduced to a minimum consistent with efficiency, and the dissection also should be limited to that barely necessary to accomplish the advancement. 2. It must be effective; that is, the globe must be rotated to and maintained in such position as is necessary to transpose the visual axis as nearly as possible to the primary position after convalescence. The advanced tendon, in case of advancement, or the shortened tendon or muscle in case of resection or tucking, must be held firmly *in situ* and maintained in position until adhesion takes place. 3. The cosmetic effect must be good. The eye is the most beautiful of all the organs, and its

beauty must be guarded. The purpose of advancement is to improve the appearance, and straightening the eye is practically all that is ever accomplished, binocular single vision and fusion being seldom ever acquired, and an ugly scar from reckless mutilation of conjunctiva and Tenon's capsule and from redundant sutures and knots may be worse than the squinting eye, otherwise beautiful.

The object of advancement is to change the direction of the visual axis of a squinting eye back to a position parallel to that of its fellow eye, or to its primary position. To accomplish this, we change the point of application of a force which rotates the globe by acting as a fulcrum about the center of rotation of the eye. This force is the muscular force, and acts in a somewhat variable tangential plane to the globe toward the origin of the muscle. The tendinous insertion, or point of application of the force, is a variable point as compared to its origin, which is fixed, and which cannot be changed. The insertion after tenotomy or resection may be transferred forward or the same physiological effect may be had by tucking or looping the tendon without molesting its insertion.

It is difficult to discuss a method of operation without having first tried it, and I am sorry I have not had the opportunity to try that of Dr. Hulen. It has the same features as do all operations where tenotomy and resection are used, and the disadvantage over the shortening methods without tenotomy—the possibility of not advancing the muscle along a meridian of the eye directly forward from the original insertion. This may result from not placing the scleral sutures in the proper position at first or by the suture of one side cutting through, leaving the attachment more on the other side of the tendon than intended. His method has the advantage of one suture, or practically one, and of being placed previous to the severing of the tendon. The counter tension on tendon and globe by the sutures inserted is rather unique, and I should think very serviceable and convenient.

Dr. G. C. Savage, Nashville, Tenn.: I want to congratulate Dr. Hulen on his suture and condemn him on cutting the muscle. If he had not cut the muscle, but pulled it forward and tied his sutures, they would have held it in contact with the ball and it would have been a beautiful Lagleize flat advancement operation. I think if Dr. Hulen will turn to Norris and Oliver, or turn to a smaller book of mine, he will find the Lagleize operation described and then he will cease to cut that muscle in two. I did this operation ten or fifteen years ago without cutting the muscle, the thought occurring to me just as I was about to cut the tendon, and seeing the beautiful results following claimed the operation for myself, but I found that Lagleize had done it before, and I immediately gave credit for the operation to Lagleize. In connection with this operation, and any other stitch operation, let me advise you to tie your suture over a Price suture plate. It will not excite any additional irritation and it will be the easiest suture removed that you have ever seen.

Dr. F. C. Todd, Minneapolis: While I believe in the tucking operation and prefer not to cut off the loop of tendon, and believe that can be best attained by an instrument which one may have under his control, yet it is evident to me that there are some valuable features in this operation, as, for instance, the vertical suture. The objection which I wish to point out to this operation is the fact that the pull is along the fibers of the tendon so that the degree of effect produced cannot be thoroughly controlled. The fibers of the tendon going toward the cornea, the thread then to be pulled in the direction of the tendon fillers, will cause the thread to cut through and it may give way entirely. I would suggest that this objection can be overcome by inserting a suture in the edge of the tendon in the manner I do with my tucking operation, using a catgut suture which will be absorbed, so that when tied at right angles to the direction of the tendon fibers it will bind them together and then the silk sutures may be inserted back of them and thereby the silk sutures will pull against the already tied catgut sutures and so will not cut or slip. Thus there will be an anchorage against which to pull, and a more definite and permanent control over the tendon.

Dr. Mark D. Stevenson, Akron, O.: There are many things about this operation that commend it. The simple use of traction sutures is unique and helpful. The needle and doubled thread must be forced through each suture canal in every case so there is no reason why both threads should not be used. If the thread is oiled before use by some sterile ointment, it will slip through the canal more easily, will absorb and carry less fluid into the canal, with less likelihood of infection, and the two threads will occupy the canal space better than one. If one of the threads should break, the other can be used to fix the muscle on the globe. In a paper, "A Secure, Looped, Single-Stitched Advancement Suture, with a Consideration of Scleral Anchorage" *(Ophthalmology*, July, 1906*)*, I described the best position of scleral anchorages. The sclera is thickest quite near the cornea and at the muscle insertion, being thinner between these two points. I described in a paper before this Section in 1905 the single vertical suture canal, where the pull of the suture is against the side of the whole canal and not merely against the shelving anterior edge of a horizontal canal which is much more likely to be cut through by the suture. The scleral suture should be made strong enough, but anyone who will make these sutures through pigs' eyes will be alarmed to find how many of them go entirely through the sclera. I think Dr. Hulen's hold on the muscle tendon inadequate, except where low degrees are to be corrected. It could be improved by a loop on upper and lower threads of tendon, the cross part of the loop assisting in grasping the tendon fibers so as not to cut between them so readily, and also to support the traction parts of the suture.

Dr. John Green, Jr., St. Louis: If I may be permitted to speak on the basis of a single experience with this operation, I may say that the operation appeals to me as being decidedly simple. The scleral suture can be easily and exactly inserted as the tendon insertion, which serves as a landmark, has not been interfered with. In the second place, the placing of the tendon suture is equally easy. The most gratifying feature of the operation is when you ask the assistant to draw on the traction sutures, you will be surprised and gratified at the ease and exactness with which the tendon is brought into position. Finally, after the operation is completed, the apparent traumatism is hardly any greater than after a simple tenotomy.

Dr. E. C. Ellett, Memphis: It has been demonstrated recently that in these operations where the tendon of the muscle is advanced you do not advance the true attachment of the muscle at all. The muscle attaches itself solidly to the globe from the point of the new attachment clear back to where it was cut from the sclera and the true new point of attachment is the old point of attachment. You have merely shortened the muscle. If that is true, and it has been demonstrated anatomically to be true, it seems to me a great deal would be gained by abandoning this scleral anchorage altogether and fastening the stump of the cut muscle at the site of the original insertion, which is very much easier to do.

Dr. Vard H. Hulen, Houston, Tex.: If Dr. Savage has time to read my paper, he will find that I have described the procedure to which he refers, and in some cases of heterophoria, where a large effect is not necessary, I might recommend this looping operation; you can easily do it by placing and tying the sutures without severing the tendon. I have used this plan and like it in just these cases.

Dr. Todd, I think, will find that by putting the tendon suture in vertically and, as I have described, the loop under the tendon will give efficient friction clear across, and there is no tendency for the suture to cut out.

Dr. Ellett may be correct when he says the tendon is not ultimately advanced beyond its original insertion. But we know the action of these operations is principally mechanical, and certainly by introducing the suture far forward in the sclera you can get a much greater effect than by putting it in at the site of the original insertion of the tendon, and we may thus get the desired result with less sacrifice of the tendon itself. Wherever you have great disturbance of the tissues underlying the tendon, or of the tendon itself, you may get adhesions and thus fail to advance ultimately the insertion. One of the great advantages of my plan is that of putting the sutures in the sclera before severing the tendon, as you know where the insertion is and can judge the correct site for the new insertion, and not get it too high or too low.

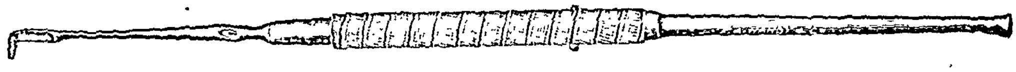
I am much gratified that Dr. Green has tried this operation in one case since the appearance of the presessional reprints and can here testify to the great usefulness of the traction sutures. If the sclera is thin, the scleral suture *must not be placed too deeply, and to broaden the loop the suture may be entered twice, thus increasing the distance between the entrance and exit of this suture, so that the tendon will not be bunched when the fixing sutures are tied.*

A NEW CARTILAGE KNIFE FOR USE IN THE SUBMUCOUS RESECTION OF THE NASAL SEPTUM

ALFRED N. MURRAY, M.D.,
CHICAGO

To obviate the danger of perforating the opposite mucous membrane when making the initial incision in the cartilage in the submucous resection of the nasal septum, I have devised a simple blunt knife not unlike a number of other knives used in various fields of surgery, which reduces the chances of this accident to a minimum. While it is true that in experienced hands the sharp knife can be used with comparative safety, many who do this operation are not so skilled, and not infrequently produce perforations. Even in the case of the skilled operator, however, the use of this protected knife will greatly simplify the making of the initial incision in the cartilage. A description of the manner of using the instrument will demonstrate its simple principle and the ease with which it is adapted to its purpose.

Having reached the stage in the operation where the cartilage is to be incised, the incision is begun in the ordinary way with the sharp knife, the finger being placed in the opposite nostril to feel the point of the knife as it penetrates the cartilage. The incision, however, is made only 2 or 3 mm. long, or just sufficient to admit the dissector point of the blunt knife. When this is in position the knife is moved at will along the line of incision, dissecting the mucous membrane of the opposite side in its course and incising the cartilage at the same time. Thus the dissection of the opposite mucous membrane is also already begun when the incision is completed.



A new cartilage knife for use in the submucous resection of the nasal septum.

Some little difficulty may be experienced in first introducing the knife, but I have found that by placing the dissector point at right angles to the line of incision and working it under the mucous membrane of the opposite side, one soon has ample space in which to direct it properly and start the incision.

The knife is, of course, not adapted to all cases, or to work far back in the nose, its especial use being to make the primary incision in the cartilage.

100 State Street.

PRELIMINARY REPORT OF WORK ON CLOT-CULTURE

LOYAL A. SHOUDY, A.B., M.D.
Senior Resident Pathologist to the German Hospital
PHILADELPHIA

After reading the work done by Gaffky, Durham, Gruber and others with the *Bacillus typhosus,* noting the dilutions to a greater or less degree, for the purpose of lessening the inhibitive power of the serum, the idea came to me that the blood-clot was the essential part in the growing of organisms from the blood. Accordingly after doing the Widal agglutination test in a case that was not a clear enteric, I was prompted, after the removal of the serum from the Widal tube, to put the small remaining clot in a tube of bouillon. This I incubated for twelve hours and then examined by means of the hanging drop. I noted many organisms morphologically characteristic of the *Bacillus typhosus.* From this tube I inoculated a tube of litmus milk, one of agar slant, one of potato and a stab of glucose agar and incubated over night. On examination the following morning I noted that the growths were all typical of typhoid.

Next day I did the same in five other cases with like results. The Widals had been collected in the ordinary manner and I was not surprised to find growths of *Staphylococcus albus.* I plated my growths and again inoculated, using litmus milk, agar, glucose, potato, lactose and litmus lactose with the same results. Later I tried the agglutination test on my recovered organisms. They clumped and I was satisfied that I had recovered the *Bacillus typhosus* from the clot.

I was at once struck with the simplicity of the method and have since tried it in sixteen other cases with equally good results, each time obtaining a growth of the *Bacillus typhosus.*

In all but three cases the Widal was positive. In two of these three cases a positive reaction was obtained later but not to date in the third. Another feature of this third case is the fact that a blood-culture taken in the usual manner gave a negative result, being sterile. In a number of these cases I obtained the organisms before a positive Widal reaction was secured.

My technic to date is to sterilize my Widal tubes and blood-sticker, wash the finger or ear carefully (in the usual way, with mercuric chlorid, etc.) collect the blood; seal the tube, shake the blood to the opposite end, place in the centrifuge for fifteen minutes or until the serum is separated, break open the tube and by means of a sterile pipette remove the serum, remove the clot and place it in a tube of bouillon, incubate twelve to twenty-four hours and then plate, inoculate, and identify the organisms. My series of twenty-one cases extends over a period of two months and with positive results in each case.

I am sure that with care one can secure negative results or sterile cultures, where the blood contains no organisms, because I have done so in three cases as a check to my work in the laboratory.

In three cases I have made a hanging drop of normal salt solution and inoculated this from the clot and noted organisms morphologically characteristic of the typhoid bacillus; and later cultures proved them to be such. I have also tried collecting the blood in a 0.2 per cent. solution of sodium citrate to prevent the clotting and compared results.

On this I will report later. At the present time I am working with cases of general infection other than typhoid with the idea that the clot is the essential part for culture work. I feel that this method of culture by clot, however obtained, will simplify blood work in general and typhoid in particular.

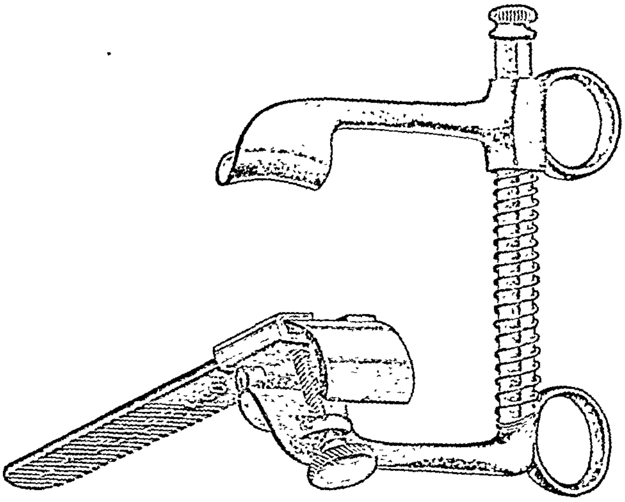
This is but a preliminary report of the work now being done in the laboratory of which I will give a complete account in the near future.

A NEW COMBINATION MOUTH-GAG AND TONGUE-DEPRESSOR

F. H. BRANDT, M.D.
BOISE, IDAHO

Because it is almost impossible for an assistant to hold the tongue down properly in operations on the throat, under general anesthesia, without being in the way of the operator, I have designed an instrument, of simple construction and easy to adjust, which keeps the tongue out of the field of operation. The objection to similar instruments now on the market lies in the impossibility of removing the tongue-depressor without taking out the mouth-gag also. This is important, as conditions may arise during an operation which necessitate the immediate removal of the tongue-depressor.

The mouth-gag is the well-known Stubbs-Murdock model, to which I have attached the tongue-depressor, working on a swivel joint, which accommodates it to the base of the tongue, so hard for an assistant to hold down. As seen in the illustration a set-screw is fastened to the lower teeth-plate which controls and fastens the tongue-blade at any angle desired, and it is not necessary, in order to remove the tongue-depressor, to touch or unfasten the set-screw. The main feature of the instrument lies in the readiness and ease in which it can be introduced, adjusted to the base of the tongue and instantly removed.



A new combination mouth-gag and tongue-depressor.

THREAD WORMS IN THE APPENDIX

REPORT OF TWO ADDITIONAL CASES

J. M. ALLEN, M.D.
ST. JOHNSBURY, VT.

A few months since I reported the finding of thread worms in the appendix of a young girl. I now wish to add two additional cases of this somewhat rare condition.

Case 1.—Dec. 11, 1909, while operating on a boy aged 4 for a right inguinal hernia the appendix was found in the hernial sac, and was, of course, removed. On opening it there were found eleven thread worms.

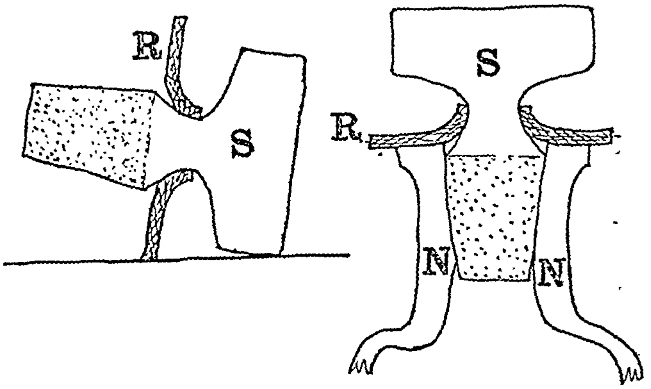
Case 2.—Jan. 15, 1910, a girl aged 14 was presented for operation by Dr. F. E. Farmer of this place. The patient gave a history of one sharp attack of appendicitis over a year ago, and several attacks of colicky pain at intervals since that time. The last attack occurred January 12. There was no rise in temperature nor increase in pulse rate but there was great tenderness and pain in the region of the appendix. The appendix was removed January 15 and appeared to be full of fecal matter. On opening it there were found a ball of thread worms in the distal end and several single worms along the walls. There were no gross changes in the walls, and it seems reasonable to suppose that the movement of the worms excited spasm of the appendix and the pain was caused in this way.

All of these cases were seen by my assistants, Drs. W. B. Fitch and F. E. Farmer.

A SIMPLE AND INEXPENSIVE DEVICE TO PREVENT THE CONTAMINATION OF STERILE SOLUTIONS

A. G. BETTMAN, M.D.
Demonstrator of Histology, Medical Department, University of Oregon
PORTLAND, OREGON

Sterile solutions are often put into carefully sterilized bottles, closed by sterile stoppers and then set away. By the time the solutions are to be used dust has collected on the lips of the bottles and in pouring out the contents the germs are washed off and the solutions are no longer sterile. Wiping the top of the bottle, at best, removes only part of the germs and drops the rest of them directly into the bottle. Then the stopper is laid down on some unsterile surface and, loaded with microorganisms, is returned to the bottle.



Sectional view of glass stopper with protective rubber collar attached. S, stopper; N, neck of bottle; R, rubber collar.

To obviate this I have devised a simple inexpensive device, so simple, in fact, that I hesitate to present it. From a piece of heavy rubber sheeting (that from a hot-water bottle answers best) cut a round piece, of such size that when placed over the mouth of the bottle the edges project somewhat. Then cut a small round hole in the center, of such size that the rubber is with some difficulty slipped over the stopper. When the stopper is now returned to the bottle the rubber covers the lip and extends a little beyond, thereby keeping off all dust. Evaporation of the bottle contents is also prevented.

A third advantage, and probably the greatest, is that the stopper may be laid down without the inner end resting on the unsterile table, as the rubber acts much the same as the rest on a carving knife. This device may be used for stoppers of any size, shape or material by varying the size of the rubber and of the hole. For an ordinary eight ounce perfume bottle I cut the rubber a little larger than a silver dollar and the center hole not over ¼ in. in diameter.

I believe that many stitch abscesses might be prevented by using this device on suture containers and on dressing jars; druggists could adapt it to advantage.

392½ Sixth Street.

EXCESSIVELY HIGH TEMPERATURE IN A CASE OF INCIPIENT PULMONARY TUBERCULOSIS

O. H. BROWN, M.D.
ST. LOUIS.

The patient in this case was in the Missouri State Sanatorium for from twelve to fourteen months. One morning, a year or more ago, the nurse brought a thermometer to me complaining that she could not tell where it registered. She said that this happened every time she shook the mercury down and returned the thermometer to the mouth of this particular patient. The nurse also complained that the patient had bitten the bulb off from one or two thermometers. On examining, I found that the mercury extended nearly to the free end of the thermometer. I was aware that a patient sometimes plays a trick on the nurse by holding the mercury bulb in the steam-jet of the radiator, so I took the thermometer and placed it in the patient's mouth and stayed by her side. Soon the patient complained that the thermometer bulb was broken in her mouth. So it was, but the mercury also filled the tube nearly to its free end, and she had not bitten the glass.

Thinking that it might have been the fault of the thermometer, I tried another, and with each the mouth temperature registered 109 to 110, or higher. The patient's rectal and arm temperatures were both normal. This observation was made on several different days. On one occasion only, and this several days after the high mouth temperature ceased, the patient's rectal temperature registered about 108.

On seeking for an explanation for this singular manifestation, it was found that the patient had several small sublingual ulcers. No bacteriologic study of these was made. She also had some decayed teeth and inflamed gums. The patient was of a hysteric type and frequently had pains and other symptoms that were unexplained except as hysteric manifestations.

I regret that I was not able at that time to make a bacteriologic examination of the ulcers, as these were possibly the cause of the phenomenon. The high rectal temperature was perhaps caused by an ulcer of the rectum against which the bulb of the thermometer came in contact.

Humboldt Building.

PROLONGED USE OF EPINEPHRIN IN ASTHMA

J. N. HALL, M.D.
DENVER

Patient.—A physician of unusual enterprise and intelligence, aged 35, an athlete weighing over 200 pounds, contracted whooping cough in May, 1903, and during convalescence from this disease began to suffer for the first time with bronchial asthma. During the summer nasal polypi were removed from the region of the middle turbinate, with much aggravation of the asthma. During the next year he was treated by prominent physicians in two of the largest American cities and in Liverpool and London, more polypi being removed in the latter city. The asthma became progressively worse so that the patient came to Denver a complete invalid in October, 1904. He had at this time no free interval of over an hour, and slept in the upright posture.

Physical Examination.—This showed pronounced general asthmatic wheezing. There was marked dulness over the upper sternal region and the voice and respiratory sounds on the right were decreased in intensity. I believe that these phenomena were due to enlargement of the tracheo-bronchial glands.

Treatment and Course of Disease.—I recommended a trial of a 1-to-1000 epinephin solution hypodermatically. The first dose of 8 minims in half a minute gave the first absolute relief from the asthma and the terrible mental depression from which the patient suffered. The tenacious mucous secretion was loosened and expectorated at once. The relief lasted two or three hours, and the patient thereafter took the remedy whenever symptoms of the return of the paroxysms appeared. During the past five and a half years he has taken about 200 ounces of the solution, at times taking from 40 to 60 doses hypodermatically in a twenty-four-hour period, generally 5 or 6 minims at a dose. He progressively lost weight until he stood at 114 pounds in January, 1910. Without any change in treatment or other circumstances which might explain it, he suddenly began to improve, and the asthma entirely disappeared in six or eight weeks. He weighs today 185 pounds and is apparently entirely well. He has, of course, stopped the epinephrin.

Attention is called to this case on account of the phenomenal amount of epinephrin used. The reports from clinical laboratories led me to fear serious damage to the arteries and heart from the long-continued use of it. The blood-pressure is normal (135 mm.), heart and arteries entirely negative, urine free of albumin, and general condition absolutely good, so far as careful examination can demonstrate. Dr. Henry Sewall confirmed these findings, and Dr. E. W. Stevens examined the retinal arteries and reported them negative as to the presence of arteriosclerosis. The dulness in the upper sternal region has disappeared. No emphysema is present.

The patient has had three attacks of suddenly developing, intense distress with emesis, headache, involuntary evacuations and profuse perspiration, and tense wiry pulse after taking his medicine. He believes that they were due to too rapid absorption of the drug, presumably from its entrance into a vein. He concludes that the remedy is best given diluted with normal saline solution and placed so superficially in the tissues as to prevent too rapid absorption, with the purpose of avoiding the frightful attacks described.

The patient exhibited himself at our local society meeting and attracted so much attention that he has given me permission to report his case.

Therapeutics

HEXAMETHYLENAMIN

Hexamethylenamin, U. S. P., is a solid crystalline substance obtained from formaldehyd. It is very soluble in water and soluble in ten parts of alcohol.

This most useful drug has been known for a number of years, and was made official in the Pharmacopeia of 1900, but its efficient activity as an antiseptic in the fluids of the body, combined with its comparative harmlessness, has not been thoroughly recognized until recently. It has been freely used as a bowel antiseptic and a genito-urinary antiseptic, but it had not been demonstrated until within the last few years how efficient it was as an antiseptic and germicide in the gall-bladder. It has been clinically positively demonstrated that it is valuable in acute infections of the gall-bladder, and efficient in preventing the development of, and the propagation of, typhoid bacilli and other bacilli in the gall-bladder. Consequently, when used during or after typhoid fever it is efficient in preventing these bacilli from remaining in the parts of the body where they prefer to harbor and perpetuate their kind, viz., the gall-bladder and the pelvis or other parts of the kidneys. Being excreted also through and into the biliary passages with the bile it acts as an antiseptic for all of the biliary ducts. When any operation on the gall-bladder is decided on, unless the operation is one of emergency, a course of several days of hexamethylenamin treatment should be inaugurated as tending to render the gall-bladder more or less antiseptic. At least it is possible with this drug enormously to diminish the bacteria in this infected region.

Crowe (*Archives internationales de Pharmacodynamie et de Therapie,* 1908, xviii, 315) showed by experiments on dogs that hexamethylenamin was excreted not only by the liver ducts into the gall ducts, but also by the gall-bladder itself and also by the pancreas. After exposure of the duodenum an opening was made about 3 cm. below the pylorus, and small catheters inserted into the orifices of the pancreatic and common bile ducts. The bile and pancreatic juice were collected after the intravenous injection of secretin. The experiments showed that hexamethylenamin is excreted in both the bile and pancreatic juice. Examination of the bile in the gall-bladder in experiments in which the cystic duct had previously been ligatured, showed that the substance is excreted directly by the gall-bladder as well as by the hepatic cells. The milk and saliva of these dogs also gave the test.

In view of the findings in animals it was determined to make a bacteriologic and chemical study of the bile obtained from patients with biliary fistula before and after giving hexamethylenamin. The number of colonies of organisms obtained from one loop of bile in all cases was rapidly reduced to zero. In one specimen before giving the drug, 150,000 colonies were obtained from one loop of the bile, while after giving the drug for a few days, the bile was absolutely sterile. The organisms found were chiefly typhi, coli and pyocyaneus. Typhoid germs are particularly susceptible to hexamethylenamin. The dose necessary to obtain the desired effect quickly in the gall-bladder was found to be 5 gm. (75 grains) a day. Usually one to two doses are sufficient to render the bile absolutely sterile.

Crowe also demonstrated what has since been repeatedly noted, viz., that hexamethylenamin is excreted into the cerebrospinal and synovial fluids. One instance was that of a boy aged 13 who had symptoms suggesting a cerebellar tumor. A decompression operation was done and the wound closed. A plaster dressing was applied, and on removing it twelve days later, a cerebrospinal fistula was found in the upper part of the incision. The discharging fluid contained a few pus cells, bacteria, and shreds of necrotic tissue. Meningitis was feared. Thinking that hexamethylenamin might possibly be excreted by this route also, the boy was given a 0.66 gm. (10 grain) dose of the drug and five or six hours later some of the discharging fluid was collected and tested. A distinct test was obtained and the dose was increased to 2.0 gm. (30 grains) a day. Three weeks later, under this treatment the fistula had closed entirely and the temperature was practically normal.

The second case was one of acute gonorrheal arthritis. The knee joint was swollen, very hot and tender. The patient was given 1.0 gm. (15 grains) of hexamethylenamin. Nine hours later the joint was aspirated and about 100 c.c. of pus withdrawn. The chemical test showed the presence of hexamethylenamin in considerable amount. The dose was increased to 5.3 gm. (80 grains) a day, and four days later cultures from the joints showed a marked decrease in the number of organisms present. A third aspiration, ten days after admission into the hospital, showed that the organism had completely disappeared, but some periarticular infiltration and some limitation of motion still remained.

In no case were ill effects noticed after the administration of hexamethylenamin, other than painful *micturition after prolonged administration.* This entirely and rapidly disappeared on withholding the drug.

At the recent annual meeting of the American Therapeutic Society, held in Washington, May 5, 6 and 7, Dr. Wilfred N. Barton, of Washington, D. C., related a number of cases of otitis media in which the suppuration rapidly healed and became sterile under the administration of hexamethylenamin.

It therefore seems demonstrated that in bowel infection, typhoid fever, and especially post-typhoid, in gall-bladder inflammations, in cerebrospinal infection, and in middle ear infection, it is scientific and logical to administer hexamethlyenamin whatever other treatment is inaugurated or deemed advisable. It has, now, long been recognized that this drug is the most valuable urinary antiseptic that can be administered, and it is, therefore, useful when the urine contains bacteria of any kind; in inflammations and suppurations of the pelvis of the kidney, in cystitis, and in urethritis.

From the observations of Crowe it would certainly seem advisable to administer this drug in gonorrheal arthritis, pneumococcic arthritis, and perhaps in tubercular arthritis. We are not aware that it has yet been shown to be of value in tubercular disease, whether of the joints, kidneys, or lungs. It certainly is worthy of investigation in this disease.

The dose of hexamethylenamin varies from 0.25 to 1.0 gram (4 to 15 grains). The size of the dose should be determined by its frequency. Probably 0.50 gram (7½ grains) is always a sufficient dose, and this dose could be administered two or three times in twenty-four hours, or 0.25 or 0.30 gram four times in twenty-four hours. It is quickly absorbed and quickly appears in the urine. Occasionally it causes slight irritation to the kidneys, and rarely has seemed to be the cause of a slight hematuria or hemoglobinuria. This, however, has occurred so rarely as to be considered instances of *peculiar idiosyncrasy.* It is, perhaps, however, unwise to administer this drug, except in much smaller amounts, when there is an acute nephritis. The writer of this editorial has used this drug in many instances for weeks or even months, and in one instance at least for two years in daily doses of the size above described without any symptoms or signs of undesired action. It can, therefore, be presumed that the drug is harmless to the digestion, nutrition, circulation, blood-making organs and kidneys.

This drug will act satisfactorily in preventing phosphaturia when all other drugs, diets and treatments have failed, and hence, can be used to prevent undesired alkalinity of the urine.

Healthy Diphtheria Bacillus-Carriers.—Lemoine inoculated tubes of coagulated serum with mucus from the pharynx of 232 individuals including 86 entirely healthy, 90 with measles and 56 with other affections. He found that the diphtheria bacilli developed in 22 per cent. of the healthy, in 37 per cent. of the measles patients and in from 30 to 47 per cent. of the others. Notwithstanding these positive bacteriologic findings no cases of diphtheria developed in the environment of any of the persons tested. Contagion occurred, however, from others sheltering the bacteria who had not entirely recovered from a preceding attack of diphtheria, some sequel still persisting. On the whole his experiences show, he declares, that no danger need be apprehended from the really healthy diphtheria bacillus carrier, but that persisting sequels of the disease seem to maintain the virulence of the germs. The development of coryza or sore throat in persons in the environment of a diphtheria patient also calls for prompt bacteriologic examination. It is scarcely necessary, he thinks, to examine the persons in the environment not in direct contact with the patient if they remain free from clinical symptoms under close supervision.—*Bull. Soc. Méd. des Hôp.*, March 19, 1910, page 160.

SATURDAY, JULY 9, 1910

HEMORRHAGE AND TRANSFUSION

The study of hemorrhage and transfusion of blood and various associated changes and conditions, as now being carried out in surgically equipped research laboratories, is producing results of much interest. The work is so intensely practical that it merits the attention of the pure clinician as well as of those who devote their energies solely to scientific pursuits.

In summing up the results already accomplished in this comparatively new field of work we find much of value. The early workers of recent times, among whom are Carrel, Guthrie, Crile and others, demonstrated the feasibility of vascular anastomosis and vascular suture. They have shown that the technic of direct transfusion from one person to another is easily mastered, can be quickly performed, and opens up a large field for future therapeutic achievements. We are already assured that direct transfusion is a life-saving measure in case of accidental hemorrhage. It is of value in the prevention and treatment of shock. It probably is of considerable aid in tuberculosis and some other chronic diseases.

Control experiments, performed with the object of comparing the value of blood and saline transfusions, tend to show that the latter has enjoyed undue prominence as a therapeutic measure; for example, in the treatment of accidental hemorrhage it rarely is a life-saving measure, whereas blood-transfusion certainly is. Indications are that the use of blood will also in a large measure supersede the use of saline transfusion in illuminating-gas poisoning.

Study of the blood elements has revealed a diagnostic point of aid in differentiating acute hemorrhage from shock; in the former, the red cells and hemoglobin are decreased, while the white blood cells undergo a distinct leucocytosis; in shock these changes do not occur.

The present-day workers are expending their energies in various directions. The injection of blood-serum for uncontrollable hemorrhage promises to yield good results. The logic of the universally accepted calcium-chlorid therapy in hemorrhagic conditions is being investigated, and in the due course of time we may hope to know, as a result of carefully planned and well-controlled work, whether such treatment is truly of value in selected cases or is to be discredited and given up.

Boycott and Douglas are doing interesting work in following out the changes which transfused blood undergoes and in studying the effects of transfusions on the organism of the recipient. They find the anatomic and histologic structure of transfused rabbits not essentially altered. The spleen is three times the normal size, the liver and kidneys slightly increased. Eosinophilic granules in the phagocytic cells of the mesenteric glands and spleen show an activity greater than normal. The organism disposes of transfused blood, they conclude, in the same way as normal animals dispose of their own "effete" red blood corpuscles. It is taken out of the circulation by phagocytic cells, chiefly endothelial in nature, in the spleen, bone-marrow and hemolymph-glands and then broken up, first into recognizable fragments, later into residue, part of which is seen in iron-containing pigment.

The work of Crile in clinical investigation of transfusion, of Carrel and Guthrie in vascular anastomosis and transplantation of organs, in conjunction with that of Boycott and Douglas and others who are concerned with the histopathologic and chemical features of the subject, promises to yield rich returns in the near future.

THE MAXIMUM OF HUMAN LONGEVITY

To continue the subject we discussed last week, it would be a matter of interest if the extreme age limit of human beings could be definitely ascertained. Instances of extreme longevity, reaching 132 years, have been reported, but according to the mortality report of the Census Bureau of Vital Statistics as prepared by Dr. Cressy L. Wilbur, most of these reports when investigated are found to be unreliable; not intentionally untruthful in many instances, perhaps, but untrustworthy because based on unverified report. This is also found to be the case in Europe, as reported by Thoms and Young. It is believed that the age of 100 has been attained, but, as Dr. Wilbur suggests, "it is perhaps doubtful whether, as shown by incontrovertible evidence, the age of 110 has ever been reached or exceeded." If it could be determined by exact observation that human beings had lived 140 or 130, or even 110 years, that fact would establish the capability of the human organism to keep up those metabolic changes which are essential to life for a period much greater than the present ascertained average or Scriptural allotment of years. Thus it would furnish a mark toward which superior eugenics and real hygienic living could aim, and the extreme limit might be attained more frequently and the average of longevity raised.

There are various theories in relation to longevity. The idea has been advanced that the human machine, in any particular instance, or in a family, is wound up to run about so long, and, barring accident, the individual life will attain approximately that length.

Another idea, advanced by Nascher,[1] is that if the period of development is not forced, and maturity not reached too soon, the period of maturity is longer and the rate of decline into old age slower and a greater age is thus attained. In the period of youth and maturity the protoplasm of the cell is more abundant: in old age the nuclei of the cells are larger in proportion to the cell-contents and there is a greater and more inflexible differentiation of the cells. With an improvement in the inherited vitality of the cell by improved eugenics, a better understanding and attainment of the correct nutritional equilibrium, and the preservation of the status by correct hygiene, the maximum span of life may be reached more frequently and the general average lengthened. What that maximum is at present can be determined only by the adoption of efficient methods of obtaining vital statistics.

In Maine and Massachusetts details in regard to the deaths of reputed centenarians are collected and the facts authenticated. As Wilbur says, physicians should be interested in such cases, and together with registration officials, should endeavor to ascertain the truth about them. Complete and reliable vital statistics would establish the present maximum of longevity, a fact of real scientific as well as popular interest.

THE BRITISH AWAKENING

"Great is truth; and it will prevail"—somewhat slowly, however. For some years The Journal has been exposing the fraud and deception connected with the exploitation of proprietary remedies and at last its campaign appears to be overcoming even the inertia of British conservatism. In a recent issue, the *British Medical Journal*[2] editorially protests against antikamnia and gives the results of The Journal's analysis published five years ago. No mention is made of the fact that the Association Laboratory demonstrated that after the Food and Drugs Act went into effect in this country the antikamnia people substituted acetphenetidin for acetanilid in the product sold in America while they retained the older and cheaper drug in the antikamnia on the British market.

The immediate cause of editorial indignation seems to be that now the British public is being circularized with the "Do-you-suffer-pain?" letters, and our conservative over-seas contemporary is constrained to object, mildly it is true, but nevertheless to object. It goes even further and deplores the fact that physicians have written testimonials for this nostrum. Of course, as the *British Medical Journal* says: "They are, it is true, American doctors; but are British practitioners guiltless in the matter?" Unfortunately they are not. On this side of the Atlantic, in fact, the most widely circulated testimonial of the antikamnia people is one credited to "Wm. Hy. Griffith, M.D., L.R.C.P., Edin.; L.R.C.S., Edin.; L.F.P.S., Glas." A gentleman answering to this somewhat elongated cognomen appears in the British Medical Directory as living in the "rare old city" of Chester, England. We also find among testimonial-givers a "Dr. Arthur Bailey Francis (Queen's College), Belfast, Ireland"; "Dr. John Arthur Diggle (Med. Ref. Globe Accident Assur. Soc., of London, England)," and "Dr. M. G. Dundas," who eulogizes antikamnia in *Medical Reprints*—whatever that may be—London, England. We read too, in one of the latest American advertisements, that "among those who have paid high tributes to their [antikamnia tablets] value and who occupy positions of great eminence, may be mentioned Dr. J. Acheson Wilkin and Dr. R. J. Blackham, practitioners of London."

Doubtless there are very many more. Yet it is probable that more American physicians than British have written panegyrics on this "headache mixture"; but that is natural. There are more American physicians than British and, besides, the nostrum, we are ashamed to admit, is an American one. As a class, however, American physicians have long since ceased to be fooled on the subject of antikamnia. The advertisements of this nostrum which appear in high-class medical journals indicate that as much can hardly be said for our British confrères. We find that up to as late as last month such publications as the *Lancet, Practitioner, Medical Press and Circular, Dublin Journal of Medical Science, Glasgow Medical Journal* and the *Journal of Obstetrics and Gynecology of the British Empire* were still carrying the advertisements of this dangerous nostrum.

We hope that this is the opening wedge. Antikamnia was one of the first "ethical proprietaries" which the Council on Pharmacy and Chemistry exposed through The Journal; since it was first shown up a host of others just as bad, if not as impudent, have been dealt with in these pages. May the *British Medical Journal*—which has already purged its pages of these frauds—take up this unsavory brood *seriatim* and it will not not be long before medical journals of the better class across the water will have as clean advertising pages as American journals of the same class already have.

REPORTS ON MEDICAL EDUCATION AND THEIR RESULTS

Two thorough investigations of the medical schools of the United States and Canada have been completed in the last few months, one by the Council on Medical Education of the American Medical Association, extending through a period of six years; the other by the Carnegie Foundation for the Advancement of Teaching, extending through the last two years.

In its report the Council on Medical Education presented a list of the medical colleges graded in three classes: Class A, including those considered acceptable; Class B, including those needing certain improvements, and Class C, those which require a general reorganization to make them acceptable.[1]

---

[1] New York Med. Jour., April 17, 1909.

[2] See comment of our London Correspondent, in London Letter, this issue.

As a result of its investigation, the Carnegie Foundation published an exhaustive report on its findings exposing defects wherever found. Hypocrisy, misstatements of fact in college announcements or otherwise, and makeshifts in the enforcement of standards received particular attention, and even some regarded as of high standard did not escape criticism. Numerous cries of "unfair," "unwarranted," "lack of knowledge." and even of "prejudice" have been raised, which show that the shoe fits pretty tightly in certain quarters. There is an adage that it is the truth that hurts. It is so in this instance. The report may be subject to criticism in some matters of detail, but those who are competent to judge—those who know the actual facts—realize that, in general, the conditions set forth in the Carnegie report are true and indisputable.

It is not surprising that one college, the St. Louis College of Physicians and Surgeons, has filed a suit for damages against the officers of the Foundation and the editor of The Journal of the American Medical Association. Possibly that was the only answer the school could make to the charges brought against it, judging from an abundance of information in the possession of the Council on Medical Education. We fear that the college will not bring the suit to trial; but, if it does the public will be made acquainted with the facts —a highly desirable result. Many colleges have taken the better course, have frankly admitted their shortcomings, are endeavoring to make the needed improvements, and planning to make the best of a bad situation.

Now that the investigations have been completed and the facts have been clearly set forth, it is to be hoped that the splendid reconstruction already begun may be carried on with increased vigor. As set forth in the report of the Council on Medical Education, medical teaching in this country should be developed as a part of our educational system, coordinating and not conflicting with the other departments of that system. Let there be a strict enforcement of a four-year high-school education as the minimum preliminary requirement; let there be well-trained, full-time salaried teachers in the laboratory branches; let there be better equipped laboratories, better clinical facilities, more bedside clinics, better courses in laboratory diagnosis, and finally, let there be at least as thorough methods of teaching in our medical schools as prevail in our standard universities and colleges of liberal arts.

Undoubtedly the faculties of the majority of colleges will attempt to develop stronger and better institutions in place of those now existing. This is evident from the reports of additions to the endowments of medical education, of the erection of new buildings, of voted increases of preliminary standards and of the eager search for better laboratory instructors. In justice to the colleges it should be said that many of these extensive improvements were planned long before the results of the investigations referred to were made public. After all, the improvements which are inspired by an actual desire to teach medicine properly are the ones which count the most. Other colleges, desiring to make improvements, heartily welcomed the investigations, since the changes which could be made to the best advantage would thereby be indicated. May this improvement and development go on until medical education in the United States is second to that of no other country!

Current Comment

A NEW PATRIOTISM

Those who have been engaged for several years in keeping toll of the awful cost in life and limb through the old methods of celebrating the Fourth of July, and who have been persistently advocating more quiet, orderly and uplifting methods, have been looking forward to this year's celebration, more hopeful than in any previous year. During the last two years, and during the last year especially, an enormous amount of comment has appeared in the newspapers and magazines, calculated to educate the public to a more sensible method of celebrating this national holiday. And from the newspaper reports from all over the country, the educational work has counted, the hoped-for change has come, and the newer method of celebration has been adopted. If the change in method of celebration of Independence Day has been as great all over the country as in Chicago, then indeed has a new era begun, and a new patriotism developed. Instead of the senseless booming and snapping of bombs and firecrackers, not only on the Fourth of July itself but for several days preceding, quiet reigned supreme. Instead of whiling away the time in thoughtless, aimless efforts to create a noise, the people assembled by the hundreds of thousands to witness parades, intelligently planned and of marked educational value; they looked on displays of flags and witnessed the marching of soldiers to the rhythm of inspiring music; they saw floats representing the signing of the Declaration of Independence, the birth of the American flag, the inauguration of the nation's first president and other historic incidents of which the nation, the state, and the city are justly proud. They spent the rest of the day at picnics, at band concerts, in the parks, in visiting friends and relatives—and even here the main topics of conversation were doubtless influenced by the inspiring incidents of the morning. Of more vital importance, however, was the fact that, for the vast majority of homes, the day was peacefully ended without any awful aftermath of sorrow and suffering. And the wonder is, why the old methods were tolerated so long as they were; and why the celebration of the Fourth of July had not long since been recognized as a great opportunity to develop a genuine patriotism. Such celebrations as that witnessed in Chicago, and undoubtedly in a large number of other cities, cannot fail to create a stronger national spirit, a genuine love for our country, a pride in her past achievements, and a desire to uphold her future—and surely this is patriotism.

---

UPHOLDING THE VITAL STATISTICS LAW

An Ohio physician was convicted of violating the vital statistics law by persistently refusing to report births. He was not a member of a county society, but in appealing the case to the Supreme Court he solicited financial aid from the societies. On this account the matter came before the House of Delegates of the state society. That body wisely expressed its disapproval of this violation of the law, and also of the action of those county societies which had extended aid to the physician. In effect the resolution adopted by the Ohio House of Delegates says that the vital statistics law of Ohio should be upheld by physicians and strict compliance with it insisted on. We believe this is right. A physician who refuses to comply with this law does not appreciate his responsibility or his obligation to the state. The attitude of physicians in such matters should be carefully considered. It is an axiom in the legal profession that every lawyer who has been admitted to the bar is in fact an officer of the state. In a similar way every physician who has been licensed to practice medicine in accordance with the laws of the state is in fact a health officer of that state. The state has granted him certain privileges, in addition to placing its seal of approval on him in the form of a license to practice medicine. In return for this he is under moral, and in some states legal, obligations to render a fair and proper return by promptly performing the duties his position requires. The importance of vital statistics is known better to physicians than to others, and they should be the last to resist in any way the enforcement of these laws. Hence the attitude of physicans who refuse to make returns of births or who demand the payment of a small fee by the state cannot be commended.

MEDICAL SECTS

Sectarianism in medicine has long been with us; yet, singularly enough, its literature is exceedingly limited, aside from that of a controversial and partisan character. Apparently no one has thought it worth while to inquire why medical sectarianism exists, or why each new cult, no matter how absurd its tenets from a scientific point of view, always succeeds in attracting a following. The superficial explanation that "the public likes to be humbugged" has been repeated, *ad libitum*, although it is not true; and even if it were true, it is no explanation. Mr. Flexner, in his report to the Carnegie Foundation, on American medical schools, devotes a chapter to a dispassionate review of the subject, summarizes the present conditions, and prophesies for the future. This chapter is one of the most important in the book, and is deserving of careful perusal on the part of every thoughtful physician. It is for this reason that we have copied the greater part of the chapter in this issue of The Journal.[1] Mr. Flexner's explanation of sectarianism and its underlying causes constitutes the first attempt that has been made to account psychologically and philosophically for the peculiar fact that, historically speaking, medicine, using the term in its broadest sense, has given rise to more sects than any other form of human activity—except religion. The philosopher, the psychologist, the economist, even the latter-day sociologist and anthropologist, who has considered all fields of investigation as his by right—all have overlooked the enormous influence of medicine and medical sects on our social organism. It would be interesting to speculate on what might have been the differences in our present social, economic and educational systems and conditions, had sectarianism in medicine never existed. Only by a thorough understanding and an accurate appreciation of the causes underlying sectarianism in medicine, can we hope to evolve a permanent system of rational, legal regulation to take the place of the existing illogical, inequitable and constantly changing patchwork of compromise and legislative stupidity, which makes up most of our existing system of state regulation. Flexner's contribution will help to make such an understanding possible.

FOURTH OF JULY ACCIDENTS

Although, as stated above, new methods of celebrating the Fourth of July seem to have largely superseded the noisy, unenlightened methods heretofore in vogue, we must not be too confident of the future. Possibly nothing has been so effective in bringing about this new order of things as The Journal's annual presentation of the net results of the older methods. Furthermore it will be particularly interesting this year to show what effect these new methods have had in diminishing the numbers of killed and injured. The Journal will therefore gather statistics of Fourth of July casualties, as in previous years, and again asks the cooperation of its readers. It is hoped that each reader of The Journal will report any accidents that come to his knowledge. Complete details are particularly desired regarding all cases resulting in tetanus or death. Special blanks for such reports will be sent on application.

Medical News

CALIFORNIA

Health Conditions in the State.—That health conditions are improved is shown from the records of the State Board of Health. In 1909, 30.985 persons died as against 31,278 in 1908, and 31,095 in 1907; births and marriages show an increase over the previous year. The births reported in 1909 numbered 30.882; in 1908, 28,077, and in 1907, 24,647. The marriages during 1909 numbered 22,917; in 1908, 21,734, and in 1907, 23,000.

Care for the Insane.—The State Lunacy Commission at Sacramento has raised the salaries of the superintendents of the five state asylums and of the superintendent of the Sonoma Home for Feeble-minded Children. Dr. Hatch, secretary of the commission, states that commitments to the State Hospital for the Insane have been large this year, due to the increasing immigration and the use of alcohol. The state board is endeavoring to secure an amendment to the present law governing the commitment of the insane, and the legislature will be asked to create a fund for the establishment of a special building at one of the asylums for the care and treatment of inebriates and drug habitués.

---

[1] Department of Medical Economics, p. 147.

CONNECTICUT

Personal.—Dr. Robert S. Clark, New Haven, has been appointed intern in the House of Mercy Hospital, Springfield, Mass.

New Dean for Yale Medical School.—Dr. George E. Blumer, professor of theory and practice of medicine, is to be the new dean of the Yale Medical School, to succeed Dr. Herbert E. Smith, who has been dean for twenty-five years.——A silver loving cup was presented to Dr. Smith at the Yale Medical Alumni Association banquet, June 20, and he responded to the toast, "Twenty-five Years of the Yale Medical School." The toastmaster of the evening was Dr. Edward R. Baldwin, Saranac Lake, N. Y.——The ninety-seventh anniversary of the founding of Yale Medical School was held in the College Street Hall, June 20. The annual address in medicine was delivered by Dr. William T. Councilman, professor of pathology in Harvard University.

DISTRICT OF COLUMBIA

New Doctors for Army.—Forty-five members of a class of fifty physicians who have taken the course of instruction at the Army Medical School, Washington, D. C., successfully completed their work, June 1, and were awarded commissions as first lieutenants in the medical reserve corps of the army by the secretary of war. Surgeon-General George H. Torney presided and the principal address was made by Dr. Victor C. Vaughan, Ann Arbor, Mich.

ILLINOIS

New Sanitarium.—Contract has been let for the new Memorial Sanitarium at Charleston, to be known as the Mack A. Montgomery Memorial Sanitarium.

License Revoked.—At the meeting of the State Board of Health, June 24, the board revoked the license of Dr. David Apfelbaum, Chicago, for advertising under a fictitious name.

State Civil Service Examination.—Secretary Joseph Mason, of the State Civil Service Commission, has announced the successful candidates in the promotional examination for physicians in the various state institutions. There were ten successful candidates for promotion to physician and twelve to assistant physician.

Fraudulent Diplomas.—On June 24, Judge Landis, in the United States District Court, sentenced Dr. Alexander Chittick, Chicago, to serve sixty days in the county jail for the fraudulent use of the mails in connection with the sale of diplomas from the Chicago Medical University and the Crescent Medical University. Dr. Chittick's license was revoked by the State Board for this offense May 24.

State Board Rules Against Night Schools.—The Illinois State Board of Health adopted a ruling, June 21, that it would not consider in good standing any medical college which after June 30, 1911, offers, during the evening or at night, all or the major portion of the clinical and hospital instruction or of the didactic work such as is commonly embraced in the third and fourth years of the medical curriculum.

Personal.—Drs. William Plumer and Frank Robb have been appointed township physicians at Farmington.——Dr. William E. Miller, Columbus, was appointed physician for Adams County, June 15.——Dr. Augustus R. Reder has been appointed city health officer at Aurora.——The late Dr. Jacob H. Huber, Pana, has bequeathed $50,000 to his home city for benevolent purposes.

Reorganization of Antituberculosis Association.—The Illinois State Association for the Prevention of Tuberculosis, said to have been practically out of existence since 1906, was reorganized at a meeting in Chicago June 25, under the call of the Chicago Tuberculosis Institute. An effort will be made to arouse an interest in the formation of county and other local organizations, and an appropriation will be asked from the state legislature for a traveling tuberculosis exhibit, and for a law creating a state sanatorium. Gov. Charles S. Deneen was elected honorary president; Dr. William A. Evans, Chicago, president; vice-presidents, Drs. Tully O. Hardesty, Jacksonville, and George T. Palmer, Springfield; secretary, Frank E. Wing, Chicago; treasurer, David R. Forgan, Chicago; medical members of the central council, Dr. J. W. Pettit, Ottawa; Drs. Theodore B. Sachs, Ethan A. Gray and George W. Webster, Chicago, and Dr. St. Elmo M. Sala, Rock Island.

Chicago

Free Tuberculosis Hospital.—The Chicago Fresh Air Hospital, 7528 Northwestern avenue, exclusively for tuberculous patients, opened July 1. Treatment will be free. The hospital is equipped with two open air sleeping porches and indoor accommodation for more advanced cases. The grounds comprise twenty acres.

Endowment for Medical Research.—By the will of the late O. S. A. Sprague, the Sprague Memorial Institute for Medical Research will be established with an endowment of $1,000,000. The first step in organization has been the securing of a charter, July 1, by the trustees, A. B. Bartlett, Charles L. Hutchinson and Albert A. Sprague.

Personal.—Dr. Alice Hamilton, a resident of Hull House, has been granted the honorary degree of M. A. by the University of Michigan.——Dr. W. H. Holmes has been appointed bacteriologist to the State Board of Health to succeed Dr. N. E. Wayson, resigned.——Dr. N. E. Wayson has been appointed a physician in St. Francis Hospital, Wichita, Kan.——Dr. Robert H. Babcock, Chicago, has been given the degree of LL.D. by the University of Michigan.

IOWA

Bierring Goes to Drake.—It is reported that Dr. Walter L. Bierring, former professor of the State University of Iowa College of Medicine, will move to Des Moines, where he has accepted the chair of medicine in the reorganized College of Medicine of Drake University. He will be provided with two salaried assistants, in clinical diagnosis and in pharmacology.

Medical Society Meetings.—Jones County Medical Society held its regular semi-annual meeting in Anamosa June 9 and elected the following officers: President, Dr. Aram G. Hejinian, Anamosa; vice-president, Dr. Aileen B. Corbit, Wyoming; secretary-treasurer, Dr. John E. King, Anamosa, and delegate, Dr. Thomas M. Redmond, Monticello.——The Des Moines Valley Medical Association met at Ottumwa, June 23, and elected the following officers: President, Dr. Lawrence W. Littig, Iowa City; vice-presidents, Drs. Lewis A. Rodgers, Oskaloosa, and Ernest C. McClure, Bussey; secretary-treasurer, Dr. Fred W. Bowles, Ottumwa, and censors, Drs. Smith A. Spilman, Ottumwa; Jerry A. Replogle, Udell, and Henry C. Young, Bloomfield.

KANSAS

Personal.—Dr. H. A. Dykes, Lebanon, has been elected secretary of the Kansas Board of Medical Registration and Examination to succeed Dr. F. B. Hatfield.——Dr. Albert S. Ross, Sabetha, the newly appointed member of the board, was elected president.——Dr. Oscar R. Troje, Kansas City, has entered government service in the Canal Zone.

Meeting of State Health Officers.—At the meeting of the Association of Public Health Officers, held at Topeka, June 15, Dr. Clay E. Coburn, Kansas City, was elected president to succeed Dr. Charles H. Lerrigo, Topeka. Dr. Benjamin J. Alexander, Hiawatha, was elected vice-president. The following were reelected members of the advisory board: Dr. F. O. Marvin, sanitary adviser, Lawrence; Dr. William C. Hoad, sanitary and civil engineer, Lawrence; Dr. E. H. S. Bailey, chemist, State University, Lawrence; Dr. J. T. Willard, Agricultural College, Manhattan; Dr. L. E. Sayree, State University, Lawrence; Dr. Robert S. Magee, Topeka; Dr. Sara E. Greenfield, Topeka; Dr. W. J. V. Deacon, statistician, Topeka, and Dr. Samuel C. Emley, lecturer, Lawrence. The association declared that measles, infantile paralysis, typhoid fever and ophthalmia neonatorum are henceforth to be reportable diseases. Ex-Senator J. E. Brewer, Abilene, appeared before the board with a copy of resolution adopted by the Merchants Association to the effect that when the rules of the board operate in restraint of trade and to no benefit to the consumer they should be dispensed with. The next meeting will be held in Hutchinson in September.

KENTUCKY

New Hospital Located.—The new city hospital for Louisville is to be located on the present site at Floyd and Chestnut Streets.

Society Meetings.—The Southwestern Kentucky Medical Society met at Paducah recently and elected the following officers: President, Dr. John Q. Taylor, Paducah; vice-presidents. Drs. George W. Payne, Bardwell, and Quintus L. Shelton, Paducah; secretary, Dr. E. C. Reynolds, Paducah; treasurer, Dr. Vernon Blythe, Paducah, and historian, Dr. Robert T. Hocker, Arlington.——Under the auspices of the Lincoln County Medical Society, the local board of health at Goshen held a public meeting, at which health questions were discussed in a popular way by various physicians of the county society.

Personal.—The State Board of Control June 18 elected Dr. Henry P. Sights, Paducah, superintendent of the Western Asylum for the Insane, Hopkinsville, to succeed Dr. Thomas W. Gardiner, who has become a member of the board of control. Dr. Sights is the present health officer of Paducah, and was for three years first assistant physician at Hopkinsville.——Dr. Llewellyn P. Spears, Louisville, has been made jail physician to fill the vacancy made by the resignation of Dr. Samuel H. Garvin.——Dr. S. J. Smock has been elected health officer at Glasgow to fill the unexpired term of the late Dr. Richard E. Garnett.——Dr. Henry Enos Tuley and family, Louisville, have gone to Europe to remain until September.

MARYLAND

Personal.—Dr. Marshall West has been appointed health officer of the First District, Baltimore county, vice Dr. Arthur H. Mann, resigned, on account of ill-health.

School to Be Enlarged.—It is announced that the recent legislative appropriation of $150,000 for the Maryland Training School for the Feeble-Minded, will enable that institution to care for 200 additional patients.

Bequest of Hahnemann Portrait.—The late Dr. Alfred Wanstall, homeopathic physician, bequeathed a bust and portrait of Hahnemann and his medical books to the Maryland State Homeopathic Society, and all his medical instruments and drugs to the Homeopathic Hospital.

Monument to Dr. Horace H. Hayden.—A monument was unveiled at Windsor, Vt., his birthplace, June 25, in honor of Horace H. Hayden, M.D., the "Father of Dental Science." He came to Baltimore in 1800, joined the Medical and Chirurgical Faculty in 1810, took part in the organization of the Maryland Academy of Sciences, delivered the first course of dental lectures in the University of Maryland in 1837, founded the first dental college and society in 1840 and the first dental journal in 1841. He was an uncommon genius, an indefatigable student and investigator, particularly in geology and botany. He collected a valuable cabinet of minerals, now at Roanoke College, Va. He was twice honored with the M.D. degree, by Jefferson College and by the University of Maryland. He served as surgeon with the troops defending Baltimore in 1814. The Baltimore College was represented at Windsor by Dr. B. Holly Smith, the dean, who delivered the address.

State Society Notes.—The Medical and Chirurgical Faculty has assumed financial management of its *Bulletin,* which was begun two years ago by Dr. Henry O. Reik, who conducted it with much credit. The present staff are Dr. Emil Novak, editor; Dr. Joseph A. Chatard, associate editor; Dr. Arthur P. Herring, business manager. The *Bulletin* recommends that there be a medical man on the staff of every daily newspaper to exercise oversight in medical matters. This is necessitated by the constantly increasing importance of medical and health news and the lamentable frequency with which such news is incorrectly presented or distorted.——The semi-annual meeting of the state society will be held at Annapolis about the middle of September.——Drs. J. McPherson Scott, Hagerstown, and Henry M. Fitzhugh, Westminster, were elected medical examiners for Maryland. The Medical and Chirurgical Faculty will hereafter elect its officers in general meeting, the nominations to be made in the House of Delegates.

Baltimore

Personal.—Dr. Charles W. Mitchell has sailed for Europe.——Dr. Franklin P. Mall has gone to München, Germany.——Dr. J. Burr Piggott has assumed charge of University Hospital as superintendent, vice Robert P. Bay, resigned.——Dr. William W. Russell left for Chester, Nova Scotia, June 29.——Dr. C. Urban Smith has resigned as professor of medicine and diseases of the stomach at the Maryland Medical College.

Food and Drug Law.—The State Board of Health, on July 1, took up the enforcement of the new pure food bill, which became effective then. The legislature appropriated $15,000 for expenses. The act prohibits the sale of any drug or food that is adulterated in any way, unless the fact is stated on a label showing the percentage of adulteration. Although the act became effective July 1, it does not apply to foods and drugs purchased by the dealers prior to the passage of the act, until Jan. 1, 1911, thus giving dealers ample opportunity to dispose of all goods which do not come up to the requirements of the law. It is believed that the druggists welcome the law.

NEW YORK

Personal.—Health Commissioner Fronczak, Buffalo, left June 26 for Europe, where he will study open air schools and attend the conference on school hygiene in Paris.——Dr. John Parmenter has been elected president of the health board at Geneva.——Dr. and Mrs. John H. Collins, Schenectady, have sailed for Europe.

Bills Signed by the Governor.—Governor Hughes has signed bills permitting the establishment of a board of inebriety for New York City; authorizing the State Lunacy Commission to contract for the completion of the Mohansic State Hospital for the Insane at a cost of $2,000,000 and making a preliminary survey appropriation of $100,000; and placing the care of the insane during temporary commitment with the health officer. He vetoed bills providing for the reconstruction of the Long Island State Hospital, and for expenditures for the Kings Park State Hospital and the Central Islip State Hospital.

Would Ease Restrictions on Milk.—Modifications in the health board regulations as to milk are being urged by the Sanitary Milk Dealers' Association which was originated by Dr. Lederle. Among the provisions which it is desired to remove is one requiring that barns be swept in the morning before the milking is done. It is claimed that this requirement is practically a dead letter and that sweeping just before milking increases rather than diminishes the number of germs in the air that may gain access to the milk. The association also wants to sell pasteurized milk from cans like raw milk, and they want the time limit in which pasteurized milk must be disposed of increased from twenty-four to thirty-six or forty-eight hours.

New York City

White Plague Exhibit in Italian Quarter.—The charity organizations opened their tuberculosis exhibit June 20 in Grand street. The Italian consul-general made an address. The exhibit will be kept open for a month.

Floating Hospital Begins Season.—The Helen C. Juillard floating hospital for sick children, made her initial trip from Manhattan Island to New Dorp, S. I., July 5. This vessel carries children sick enough to require skilled treatment to the Seaside Hospital at New Dorp.

Personal.—Yale University has conferred the degree of doctor of science on Dr. Simon Flexner of the Rockefeller Institute of Medical Research.——Dr. A. Norton Brockway was stricken with apoplexy while attending the commencement exercises of Hamilton College.——Dr. Francis E. Butler has sailed for Europe.

New Medical Building for Fordham.—Fordham University School of Medicine has secured $100,000 for the erection of a new medical building on the university campus, consisting of three stories and a basement, 110 by 150 feet. It will be used largely as a dispensary, all the first floor and a part of the second being divided into rooms for clinics and laboratories for microscopic work. The building also provides for two lecture halls, a students' common room, etc.

New Hospital Dedicated.—The Peoples' Hospital at 203 Second avenue has recently been dedicated. Meyer Grenbaum made the address and stated that the funds had been raised entirely by the Jews. He stated that there were at the present time in New York city 1,250,000 Jews and of that number less than 5,000 could be cared for by the Jewish hospitals of the city. He upbraided his race for not having fulfilled the contract that they made with the Colony of New Amsterdam by which they agreed to care for their own sick and destitute.

PENNSYLVANIA

Personal.—Dr. Harry B. Adams, Media, has been appointed chief house surgeon at the Metropolitan Hospital, New York.——Dr. William S. Vanneman, formerly of Pennsgrove, has come home after having spent twenty years as a medical missionary in Persia.

Dickson City Epidemic Halted.—Within the past few days no new cases of smallpox have been reported in Dickson City. The physicians from the State Department of Health, the Dickson City Board of Health and the seven physicians employed by the borough were kept busy vaccinating the residents of the stricken city, and are now confident that the epidemic is well under control.

School Medical Inspection.—The Wilkes-Barre school board has adopted Dr. S. P. Longstreet's plan for a medical examination of all pupils twice a year. Dr. James T. Williams has been appointed chief medical inspector and his salary fixed at $1,000 a year. Pupils will be examined at the beginning of each term and at the spring vacation. Teachers will also be instructed how to determine physical defects in pupils.

Philadelphia

Addition to Hahnemann Hospital.—Ground was broken June 25 for the erection of a four-story $40,000 addition to the Hahnemann Hospital at Fifteenth and Race streets.

Infant Mortality Campaign.—Active work was begun July by the new child health division of the Department of Public Health and Charities, under the direction of S. W. Newmayer, who is in charge of the infant mortality work of the department. Eight visiting and one supervising nurse began an active campaign to reduce the death-rate among children, particularly in the congested sections.

Measles Delays Panama Liner.—Development of a case of measles on board halted the Panama liner *Alliance*, July 1, when fifty miles down the coast on the way to the isthmus. The steamer returned to quarantine, and the patient was removed to the hospital on Hoffman Island with another child which was exposed to the infection. The steamer resumed her way the following day.

TEXAS

Site for Quarantine Home.—The War Department has ceded a portion of its reservation on Pelican Spit at Galevston to the government health department for a site for the new quarantine station. About $200,000 is at present available for the work.

Society Meeting.—At a meeting of the Taylor County Medical Society held on June 27, in Abilene, Dr. Charles M. Rosser, Dallas, delivered an address on "Cancer of the Uterus." A dinner was given in honor of Dr. Rosser at the Hotel Grace. Covers were laid for thirty.

College Commencement.—At the commencement exercises of the Medical Department of the University of Texas, Galveston, May 31, medical degrees were conferred on a class of fifty-seven by President Mezes. The principal address was delivered by Dr. Ashley W. Fly, Galveston, a member of the board of regents.

Personal.—Dr. George M. Decherd has been appointed health inspector at Austin.——Dr. Edward Scott has been appointed county health officer at Bay City to succeed Dr. Bat Smith, who has resigned.——Dr. John F. Y. Paine, professor of obstetrics and gynecology in the medical department of the University of Texas, was presented with a loving cup by the senior class, June 1.

Fraudulent Instructor.—The El Paso County Medical Association warns physicians to look out for a man speaking broken English, weighing about one hundred and eighty pounds, and pretending to give courses in bacteriology and pathology to physicians. It is said that he knows but little of the subjects, and at El Paso he forgot to pay his hotel bill. The society wishes to have him located.

GENERAL NEWS

New Chief for Leper Colony.—Dr. James H. Biggar, former chief of the Culion leper colony in the Philippines, has resigned from the service and will take up the practice of medicine in Texas. He has been succeeded by Dr. Paul Clements, medical inspector of the bureau of health.

Annual Conference of American Hospital Association.—The twelfth annual conference of the American Hospital Association will be held at the Planters' Hotel, St. Louis, September 20, 21, 22 and 23. An extensive and interesting program has been arranged for the meeting.

Epidemic of Smallpox in Mexico.—An epidemic of smallpox is reported to have been raging for several months in the district of Ozumba, Northern Chihuahua, Mexico, and an appeal has been made for medical officers and soldiers to enforce quarantine laws. It is reported that over six hundred deaths have occurred in six months.

Appointments and Promotions at Rockefeller Institute.—The directors of the Rockefeller Institute for Medical Research announce the following promotions and appointments for the year 1910-1911: Laboratory Staff—Jacques Loeb, Head of Department of Experimental Biology. Associates, W. A. Jacobs, biologic chemistry; D. R. Joseph, physiology and pharmacology; Peyton Rous, pathology; B. T. Terry, protozoology; D. D. Van Slyke, biologic chemistry. Assistants, M. T. Burrows, experimental surgery; P. F. Clark, bacteriology; I. S. Kleiner, physiology and pharmacology; Hardolph Wasteneys, experimental biology. Fellows, F. J. Birchard, biologic chemistry; F. B. La Forge, biologic chemistry. Scholar, J. Bronfenbrenner, pathology. Hospital Staff—Resident physician, G. Canby Robinson. Interns, George Draper, H. K. Marks, F. W. Peabody, H. F. Swift. General manager, Jerome D. Greene.

International Congress of Medical Electrology and Radiology.—The fifth international congress for discussion of these branches of the medical sciences is to meet at Barcelona, Spain, September 13 to 18. Among the topics to be discussed are the unification of methods of electrodiagnosis, electricity as an antiphlogistic agent, the biologic action of high-frequency currents, the therapeutic action of the uninterrupted current and the electrolytic introduction of medicinal ions, the use of [illegible] in abdominal diagnosis and autoconduction. [illegible] committee in charge of the congress includes among its twenty-five members C. Beck of New York and S. Leduc of Nantes. Dr. C. L. Leonard, 112 South Twentieth street, Philadelphia, Pa., is the representative for this country. He is to present an article on the progress realized in Roentgen diagnosis to date.

National Confederation of State Medical Examining and Licensing Boards.—At the twentieth annual meeting of this confederation held in St. Louis, June 6, the following officers and committees were elected: President, Dr. J. C. Guernsey, Philadelphia; vice-presidents, Drs. James A. Egan, Springfield, Ill., and Charles A. Tuttle, New Haven, Conn.; secretary-treasurer, Dr. George H. Matson, Columbus, Ohio; assistant secretary, Dr. Darlington Snyder, Columbus, Ohio; executive council, Drs. N. R. Coleman, Columbus, Ohio; Edwin B. Harvey, Boston, James A. Duncan, Toledo, Ohio, A. H. Hamel, St. Louis, D. P. Maddux, Chester, Pa.; committee on clinical instruction, Drs. Henry Beates, Philadelphia, Charles A. Tuttle, New Haven, Conn., Fred C. Zapffe, Chicago, Maurice J. Lewi, New York; L. F. Bennett, Beloit, Wis.; committee on materia medica, Drs. M. G. Motter, Washington, D. C., J. C. Gurnsey, Philadelphia, George MacDonald, Washington, D. C.; committee on lay publicity, Drs. Darlington Snyder, Columbus, Ohio, Frederic Singer, Pueblo, Colo., Fred C. Zapffe, Chicago.

MANILA LETTER

(From Our Regular Correspondent)

Manila, May 31, 1910.

Medical School and Hospital

In medical circles in Manila considerable interest is shown at present in the Philippine Medical School and the new Manila General Hospital which is nearing completion. Much pride in the possession of such handsome and modern structures as those of the hospital and medical school is felt by both the American and Filipino physicians. It is expected that the building of the medical school will be completed and ready for occupancy in time for the opening of the fourth annual session, June 6. These buildings are modern serviceable types, of reenforced concrete. Especial attention has been given to sanitation, light and fresh air and the buildings are well adapted to a tropical climate. During 1908 the Philippine Commission appropriated the sum of 780,000 pesos for the construction of the hospital, which is planned on the pavilion system. At the same time there was set aside the sum of 250,000 pesos for a new medical school laboratory building to be erected on the same campus as the Bureau of Science and the hospital. These buildings are now nearing completion.

The Philippine Medical School

The Philippine Medical School is an outgrowth of the educational system instituted throughout the Philippine Islands by the Philippine Commission and it is also a natural development of the Bureau of Science and the Bureau of Health. The movement looking toward the establishment of such a school had its origin at the second annual meeting of the Philippine Islands Medical Association in 1905, at which meeting the proceedings demonstrated the great need of supplying physicians to the people of the islands. It was shown from statistics that there is an average of one physician to 21,209 of the population of the Archipelago, and that at present there is only one physician to each 430 square miles of territory. In this connection it is to be remembered that the population of the Philippine Islands is greater than that of Canada and that the density of population per square mile is equal to that of Indiana, and, deducting New York City, nearly as great as that of New York state. In view of these amazing facts one is inclined to ask whether a great proportion of the population, having done without reputable physicians so long, will take to improved medical attention or will patronize the modern physician. In the case of the Filipino physician this, to some extent, may be answered by the citation of the twelve months' career of a native graduate, a former scholarship student of the Philippine Medical School. After taking some hospital work he returned a little over a year ago to his native province and started practice in a town of a few thousand inhabitants, which up to that time had been without a registered physician. On the day of his arrival a man was shot through the stomach. The new doctor was sent for, merely, however, to give relief to the man before his expected death. The new doctor at his first serious case became scared out of his wits. However, with the moral support and the assistance of an American scout, ether was administered, rather at the protest of the relatives, and the wounds sewed up and dressed. By careful nursing the doctor was able to bring the man through, and, as a result, at once became a hero of the town. Last week one of the leading druggists of Manila received an order from this doctor for drugs, office fixtures and surgical supplies amounting to nearly $1,000, and he paid cash.

Scholarships

In order that the medical school may serve as wide a field as possible, the Philippine Commission has established "for each province in the Philippine Islands one free scholarship in the Philippine Medical School." This scholarship is competitive and entitles the successful competitor, who must be at least a high school graduate, to "the expenses of transportation to Manila, board, subsistence and maintenance while in Manila attending the Philippine Medical School not exceeding 500 pesos per annum each." In accordance with act No. 1632: "(d) Each scholarship student who shall graduate from the medical school with the degree of doctor of medicine, unless he shall accept appointment under the government of the Philippine Islands or one of its branches, shall return to his province and practice medicine and surgery therein for a period at least equal to the time of his scholarship tuition, unless permission to do otherwise be granted by the Secretary of the Interior. Failure to comply with the terms of this section shall be deemed sufficient grounds for revocation of his license to practice medicine and surgery in the Philippine Islands in the same manner as are other offenses described by section 8 of act numbered 310."

Entrance Examinations

During the past week entrance examinations of the Philippine Medical School have been held. These examinations are made necessary because the schools throughout the provinces are not of a uniform grade and the different colleges are too often deficient in their science instruction. There were 34 applicants.

LONDON LETTER

(From Our Regular Correspondent)

LONDON, June 25, 1910.

Annual Meeting of the British Medical Association

The seventy-eighth annual meeting of the British Medical Association, which will be held in the University of London July 22 to 29, promises to be one of the most important and successful functions of the association, both from the scientific and social standpoint. It is many years since the annual meeting was held in the metropolis, which contains a population equal to that of some European countries and is the center of medical as of all other activities in the country. The scientific business will not commence until July 26, when President-Elect H. T. Butlin will deliver his address. Among the social functions is a *conversazione* at the Guildhall given by the lord mayor and corporation.

Tetanus and the Motor Car

The statistics of recent years show a great increase of the number of deaths from tetanus in spite of the use of antitetanic serum and increasing knowledge of the mode of invasion of the disease. In the years 1889 to 1900 the average number of deaths in England and Wales from tetanus was between 30 and 40. In 1900 the number rose to 66, but fell to 57 in 1901. In 1902 an extraordinary increase occurred, the number reaching 201, and this high level has since been surpassed. From 1903 to 1908 the figures are respectively 257, 257, 248, 254, 226 and 180. The *British Medical Journal* suggests that the cause for this extraordinary increase is the motor car. It might at first be thought that the great development of motor traffic of recent years would have an opposite effect, for the concomitant reduction of the number of horses in the streets and roads would diminish the amount of animal excreta lying on them. But simultaneously the distribution of the excreta which remains has been greatly increased by the dust-raising powers of the motor car and the germs have been spread far and wide. To this greater distribution it is suggested that the increase of cases of tetanus is due. The slight fall in 1908 may be due to the fact that the supply of horses is rapidly diminishing in recent years, now that it has been proved that mechanical traction is commercially superior to horse traction.

Typhoid-Carriers in India

The annual report of the sanitary commissioner of India for 1908, which has just been published, shows that while inquiries to trace the source of outbreaks of typhoid fever in the army to water, food, etc., usually failed to yield definite results, the disease was traced to typhoid-carriers in many stations. At Wellington the search was carried out with great thoroughness by making a bacteriologic examination of the excreta of all convalescents, thrice weekly; one man was found to have chronic typhoid bacilluria 13 months after his attack. At Sialkot the investigations revealed the grave danger which may arise from the employment of the native cooks in the kitchens. A servant in the officers' mess was found to have typhoid bacilluria and two cooks in one of the squadrons of a cavalry regiment to have a similar condition. As results of these discoveries all natives applying for the post of cook were examined and another carrier was detected. At other stations the blood was examined for the Widal reaction, which was found in some cooks. Though this does not prove that the subject is a typhoid-carrier, it was considered sufficient grounds for dismissal. Evidence is also recorded of the danger of contracting the disease from patients during the acute stage. This danger is recognized at all stations, but despite careful precautions seven orderlies became infected.

Antikamnia

After a long career of tolerance in the advertising pages of most of the medical journals of this country, including, I regret to say, some of the best, Antikamnia has at last come under editorial censure. The proprietors of this nostrum have managed with some success to appeal to the profession as vendors of an "ethical" preparation and at the same time to the public with the usual wiles of the nostrum humbug. Even the revelations published by THE JOURNAL seem to have had no effect on our editors. One journal at the very time it was publishing a series of articles denouncing and exposing quackery of all kinds and criticising with due severity the lay press for inserting fraudulent advertisements of nostrums had a running advertisement of Antikamnia. The exploiters of this preparation have gone a step too far. They have sent to women through the mail samples and pamphlets, with a letter beginning: "Do you ever suffer from pain? If so please try enclosed sample of Antikamnia tablets. Always prompt and reliable." Among the conditions for which it is claimed to be a sovereign remedy are the menopause, miscarriage pains, painful menstruation, "after debauch." It is especially recommended for Americans in London who are the subjects of "brain fag!" The *British Medical Journal* has received a shower of complaints from doctors whose wives and women patients have received these objectionable pamphlets. It reprints the analysis of this nostrum made by the Council on Pharmacy and Chemistry of the American Medical Association and published in the "Propaganda for Reform in Proprietary Medicines." Your contemporary regrets that several of the testimonials quoted appear to be from physicians and points out that one of the greatest obstacles to reform in the trade in proprietary medicines is that physicians can be found to testify to their virtues. [This subject is commented on editorially in this issue of THE JOURNAL.]

Medical Treatment of School Children in London

A conflict has been in progress for some time between the London County Council and the British Medical Association on the medical treatment of the children who attend the council's schools (the greater part of the children of London). By a recent act the medical inspection of school children was established. A large number of children were found suffering from various diseases—adenoids, otorrhea, enlarged tonsils, impetigo, ringworm, errors of refraction, deafness, etc.—which interfered with their education. It was then realized that it was of no use to make provision for medical inspection if medical treatment did not follow. Unwilling to incur the large expense which this would involve the council made arrangements with several of the London hospitals to treat the children on condition of receiving donations. To this the British Medical Association has objected that it was wrong in principle for the state to endeavor to get new services carried out on its behalf by trading on the charitable institutions of the country. A further objection is that the scheme provides only for the treatment of about a fourth of the children who require it. The association suggests that the only satisfactory method is for the council to make provision for the treatment of the children by local physicians at suitable local centers. Again, the council has made no provision whatever for the treatment of the children's teeth. As shown in previous letters, dental caries is prevalent to an appalling extent; at the age of 6 nearly 100 per cent. of children suffer from it and in each child an average of 9 teeth are affected. When the permanent teeth appear there is only slight improvement; at the age of 14 less than 15 per cent. of children are free from caries, and this percentage gradually falls until not more than 5 per cent. of adults have a perfect set. No provision has been made for the treatment of children's teeth for the simple reason that the dental hospitals have declined to undertake it and have informed the council that the only method is to establish school-clinics for the purpose.

PARIS LETTER

PARIS, June 24, 1910.

Vital Statistics of France for 1909

The *Journal Officiel* has just published the annual vital statistics of France for 1909. The number of births was very small; in fact, only 769,969 live births were recorded, in place of 791.712 in 1908, a diminution of 21,743. The excess of births over deaths was only 13,424, being less by 33.017 than in 1908, when the excess was 46,441. At least a third of this diminution in the excess of births was due to the fact that there were 11,274 more deaths in 1909 than in 1908, the remaining two-thirds being due to the actual diminution of the number of births. In the first semester of 1909 the number of deaths was greater than the number of births by about 28,000; but a fortunate compensation occurred in the course of the second semester, in which there was an excess of 41,524 births, thanks to the lowering of the mortality. As for the share of the various departments in the French birth-rate, it is stated that the only regions where the birth-rate is gaining over the death-rate are the regions of the north, Brittany, the eastern frontiers, the Limousin and Corsica. On the other hand, in the departments of the Garonne and the Rhône valleys each year there are more deaths than births recorded, so that depopulation increases from year to year. In the Department of the Seine there were recorded last year 73,466 births and 74,576 deaths, an excess of 1,110 deaths. While the population of France remains, so to speak, stationary, that of Germany is increasing annually by more than 900.000, that of Austria by more than 300.000, that of England by more than 400.000, that of Italy by more than 400,000. Doubtless the diminution in the birth-rate is far from being a phenomenon peculiar to France, but in the other countries this diminution has not yet attained the same proportions; and, moreover, thanks to their previous headway, these other states preserve a large excess of births. While the average annual excess of births over deaths for each ten thousand inhabitants, or the increase in the population does not exceed 18 for the last five-year period in France, it amounts to 106 in Italy, 113 in Austria, 121 in England, 149 in Germany and 155 in the Netherlands. In other words, the annual increase in population is six to ten times more rapid in the other countries than in France. The number of marriages has also diminished in France. In 1909 there were registered only 307,951 marriages, while the preceding year there were 315,928 and in 1907 314,756. The number of divorces has continued to increase since 1900. There have been, in fact, 12.874 divorces during the last year, against 11,515 in 1908, an increase of 1,359 divorces. There were only 10.938 in 1907, 10,573 in 1906 and only 7,157 in 1900.

Improved Vaccination Against Typhoid

On June 21 Dr. H. Vincent, professor at the school of military hygiene at Val-de-Grâce, read before the Académie de Médecine an interesting communication on vaccination against typhoid fever. The vaccine prepared from dead bacilli by Wright and Leishman, while efficacious, arouses local or general reactions which are often painful. Dr. Vincent, after numerous attempts, prepared a vaccine by autolysis of the living bacilli in physiologic salt solution cleared by centrifugation and sterilized by agitation and mixed with ether. The ether is easily disposed of by evaporation at 37 C. for a few minutes. The vaccine is not heated and no antiseptic is added to it. It is perfectly limpid and is easily absorbed. Used on animals, this vaccine has shown high protective qualities. To immunize human beings Dr. Vincent has used a polyvalent vaccine prepared with eight strains of typhoid and paratyphoid bacilli. This vaccine, which was injected into 13 adult subjects under the skin of the side, was well tolerated and caused only a slight local pain without fever. It was absolutely inoffensive. The serum of the subjects so vaccinated shows very energetic bactericidal properties. In contact with it the Eberth bacillus became deformed, smaller, granular, irregular and unrecognizable. It is active for paratyphoid as well as for typhoid fever and causes a large production of specific antibodies which renders its use of great value for the prevention of typhoid fever.

BERLIN LETTER

(From Our Regular Correspondent)

BERLIN, June 16, 1910.

German Society for Protection of Infants

May 20 and 21 the second session of the German Society for the Protection of Infants occurred at Munich with a large attendance. The first subject of discussion was the measures which are included in the imperial insurance law for the protection of infants. The provisions that have been introduced in this bill were regarded as in part insufficient. A demand was made that it should be made obligatory on the Krankenkassen to provide for puerperal patients as follows: 1. A weekly allowance up to the amount of the sick relief money for eight weeks, of which at least six must fall in the period after delivery. 2. Service of a midwife and medical treatment for symptoms during pregnancy. 3. Aid on account of pregnancy in case of inability of the pregnant woman to work, amounting to the sick relief money for the entire time of six weeks. 4. In addition to the puerperal aid, a nursing payment amounting to the sick relief money to be paid to the nursing woman as long as she nurses her new-born child up to twelve weeks after delivery. The amount of the nursing money is to be correspondingly diminished if the nursing money and the puerperal money exceed the amount of the regular wages. The expenses which would arise in carrying out these demands would be small in comparison to the object to be accomplished and in view of the fact that they would lead in the end to lessened expense on the part of the Krankenkassen. They amount to 22 cents (90 pfennigs) per head of the insured for the nursing payment and 10 cents (40 pfennig) per head for the midwife and medical services.

There was also considerable debate on the removal of the evils connected with the German wet-nurse system. It was demanded that the furnishing of wet nurses should be placed under the supervision of the state. So far only one state in Germany, viz., Hamburg, has regulated wet nursing by law and there a physician is in charge of the matter. According to Professor Schlossmann it would be best to forbid the furnishing of wet nurses by private parties altogether, and turn the matter over to the foundling asylums. The foundling asylums are best prepared to form a safe judgment as to the health and nursing capacity of the wet nurse and particularly to decide whether she is free from syphilis or not. On the other hand, the wet nurses should also be protected in their rights, for instance against infection by the child they nurse. It should also be provided that a mother shall offer herself as nurse only when she has nursed her own child for three months. The foundling asylum should oversee and provide for the nurse's child for two years. The asylums should make regular reports to the authorities in charge, regarding the children of the nurses. In the discussion much stress was properly laid on the great difficulty in the practical carrying out of these provisions. The physician would be burdened with a responsibility which he might not be able to accept. The furnishing of nurses by asylums would be very expensive. It would be best, if on the whole there were no wet nurses; reference was made to America, where wet nurses are said to exist no longer. For the displacement of the wet nurses, the so-called nursing women (*Stillfrauen*) should be recommended, healthy women, known to the physician, who go to the house of their employer several times a day and nurse the child without completely depriving their own child of breast milk.

Finally, the subject of infant hygiene in the country was taken up, especially the question of the cooperation of physicians and midwives in the prevention of infant mortality. As a chief cause of infant mortality in the country, errors of diet and the indolence of mothers were given. Where the infants are breast fed, the mortality in the country is small. Essentially the propaganda is one for nursing reform and this can be most efficiently carried on by the midwives. The nursing premiums given to the midwives have proved very useful in this respect in small cities; 13 cents (50 pfennig) after six weeks' nursing. To avoid contradiction in the advice of physicians they should be required to employ a circular of instruction. Milk kitchens are indispensable in small cities. The introduction of trade guardianship, regulation of the system of boarding out children, the erection of institutions for sick infants and the improvement of the housing conditions are especially needed in the small cities. It is not practicable to extend the present arrangements for the care of infants in the cities to the open country. In the country nursing premiums are not necessary, as there the women as a rule have time for nursing. It is important to improve the method of inspection of the dead, as carried out in the country: the cause of every death should be exactly determined.

Personal

Privy Councillor Goldscheider has been selected as the successor of Professor Senator. Goldscheider has been until now director of the department for internal medicine of the Rudolf Virchow Hospital, which was opened under his direction. He is very glad I am sure to exchange this position for that of the directorship of the university medical policlinic. The numerous administrative demands which are made on the director of a hospital, especially so large a one as the Virchow Hospital, require so much of a clinician's time, that it is easy to understand his dissatisfaction with his present place. Moreover in such a position conflicts with the authorities are very apt to arise and in this case with the municipal authorities, and as Goldscheider possesses a somewhat excitable temperament such conflicts have occurred to a greater extent than was agreeable to him.

The filling of the chair of ophthalmology at Heidelberg which Professor Leber resigned on account of his advanced age has caused some difficulty. Professor Hess, of Würzburg, and Professor Axenfeld, of Freiburg, refused the call, but now it has been accepted by Professor Wagenmann, of Jena.

Dedication of the New Building of the Kaiser Wilhelm Academy

June 10 the new building of the Kaiser Wilhelm Academy for the instruction of military surgeons was dedicated in the presence of the Kaiser and the Empress and many ministers and other officials. The institution is designed, as its name indicates, for the instruction of students of medicine who wish afterward to serve as army surgeons in the active Prussian army. It was founded Aug. 2, 1795, under the name of the "Pepinière." The number of students has continually increased and as the old institution in all its arrangements was no longer suitable to modern requirements, the corner-stone of the new building was laid five years ago. The building is arranged for the accommodation of about 500 students. Like all other students they attend the lectures of the university and are expected to follow the same course in general, but in the academy they are also instructed, especially by lectures and practice, in military surgery and hygiene. Laboratories for scientific investigation are also provided. The new building, which was erected at an expense of $1.500,000 (7.500,000 marks), is architecturally a very beautiful edifice and one most admirably suited to its purposes. A series of valuable collections has been installed in it: a collection of drugs, one of instruments and dressings, a collection of models of apparatus for the care of the sick, for transportation of the sick, for lodging the sick, for the study of ophthalmology, pathologic anatomy and of ear and throat diseases. There is also an anatomic collection, a collection for physics, a collection for military surgery, including 750 preparations of gunshot wounds of the bones from many wars, presented by Professor v. Esmarch, and finally a library which at present contains about 68.000 volumes. Further there is found in the new building the hygienic laboratory, in which investigations on the provision of drinking water, on preserved foods for the army, on the clothing of soldiers, on methods of disinfection, etc., will be carried on. In the academy postgraduate courses for sanitary officers will be annually provided. A number of our most distinguished physicians have been graduates of the academy: Helmholtz, Virchow, Leyden, Behring, Löffler, Gaffky, etc.—which is good evidence of the excellent instruction which the youths studying military medicine receive at this place.

VIENNA LETTER

(From Our Regular Correspondent)

Vienna, June 23, 1910.

The Right to Grant the Title of Specialist

A difference of opinion has arisen recently between the medical council and the government as to the right to grant the title of specialist. For a few years endeavors have been made to regulate the question and to prevent the increase of self-styled specialists. The right to confer this title was claimed by two universities, and special examinations or at least certain studies were demanded as the minimum requirements. In the case, a doctor who had made the treatment of diseases by physical means, like massage, gymnastics, electricity, his special study, settled down in a country town and asked and received from the medical council permission to call himself "specialist for physical treatment" (*Specialarzt für physikalische Heilmethoden*) which, however, was not recognized by the district government officer. At length the right of the council to grant the title was recognized, and the right of a medical representative body to regulate the affairs of its own members has been clearly acknowledged for the first time in this country. In connection with other satisfactory achievements, like the right to settle financial disputes between practitioners and private corporations, the growing influence of medical representatives is clearly shown, proving the value of a good organization.

Benzoic Acid—A Dangerous Food Preservative

By order of the Bureau of Health of the ministry of home affairs (*Ministerium des Innern*) to whose notice several cases of adulteration of food by preservatives had come, an investigation of the question was recently conducted. The laboratory for food examination in Vienna, a government institution, has recently published the results of the investigations. It has been clearly proved that the addition of benzoic acid is necessary only to disguise either the smell or the color of articles of food which are not fit for use and which would otherwise not be procured by the public, and that thus it tends to be used in a fraudulent way. Apart from this fact, its constant use in even small doses may cause irritation of the mucous membranes of the gastro-intestinal tract. Therefore its use was condemned as a preservative and an order made to seize all articles containing such addition in a higher percentage than 0.025 per cent.

Results of Surgical Treatment of Lupus

In a publication dealing with the necessity of centralizing the endeavors to treat lupus systematically, Professor Lang, an authority on this subject, is strongly in favor of surgical treatment of certain forms of this disfiguring disease, in preference to the Finsen treatment. He has operated on 455 patients, showing in 250 instances lupus of the face. The latter cases are very interesting, as they prove that in skilled hands excellent cosmetic and functional results can be expected from surgical treatment with a minimum expenditure of time and expense in comparison with the Finsen method. The lesion in the face was in 95 cases larger than a five-shilling piece, in some instances nearly covering one side of the face. Lang, formerly head of the dermatologic department of the Vienna General Hospital, extirpated all these lupus patches and followed up the extirpation by plastic operations. Of all his patients operated on for lupus, 273 remained free from all recurrence for 16 years (the length of time that he has employed his method). Three patients had a recurrence, but outside of the field of operation, and after 12, 3¾ and 3 years, respectively; 22 of the patients had recurrence within the field of operation, which yielded to another surgical interference, with good results, while 10 had inoperable recurrence out of 455. All these 10 belong to the first half of the cases, or 7 to the first quarter, showing clearly the better results with improvement of technic and of indication. Extirpation is, of course, not always possible. Surgical removal is indicated only when the patch is well defined, which is not the case when it is in the mucous membranes. Size and number are not contraindications, but progressive anemia and grave complications of other organs contraindicate operative measures. In these cases Finsen's method is indicated. Its only disadvantages are the expense and the duration of treatment. Lang is absolutely opposed to excochleation and scarification of lupus, because of the resulting dense scars which hinder later excision or Finsen treatment. He insists that every lupus station shall be in charge of a competent surgeon dermatologist, who is capable of dealing with the cases according as they require excision, plastic operations, Finsen, hot-air or the actual cautery. Such equipments require great funds; therefore, it is better to have one large, completely equipped institute than several small ones. As the means of the Vienna Lupusheim are rather limited, the adoption of the light method alone would have sufficed to consume the funds at disposal. Therefore, the advantage of the surgical method is evident, as the resulting scars are as supple as those of the light treatment.

Correspondence

Practical Examinations for Medical License

To the Editor:—Of all the methods of raising standards, efficiency of examination is no doubt by far the best plan. I doubt whether any other branch is more exposed to a reeling off of mere patter instead of the furnishing of evidence of training than that of psychopathology and psychiatry. The differences of teaching are so great and the vocabulary seems to play such an undue part that there is no fair way to size up the efficiency of a man outside of a demonstration of what he does with an actual case. This plan was in practice when I passed my state examination at Zurich, in Switzerland, in 1890; both in psychiatry and in medicolegal work we had to examine and report on a case, which is perfectly feasible and really the only way to get around the differences of teaching and the hollowness of answers to mere abstract questions. I therefore plead for the introduction of these practical examinations as it will be as much to the interest of the public as to the interest of true efficiency of the work of our colleges.

Adolph Meyer, New York.

Director-elect of the Henry Phipps Psychiatric Clinic, Johns Hopkins University, Baltimore.

McCourt's Early Study of Cancer Treatment by Toxins

To the Editor:—A rereading of your editorial on "Dr. Hodenpyl, a True Scientist" (The Journal, May 14, 1910, p. 1618), and the article of J. W. Vaughan (May 7, 1910, p. 1510) describing the treatment of cancer by the cancer residue, recalls to my mind the earlier work of Dr. P. J. McCourt. Dr. McCourt for a long time treated malignant neoplasms by a diluted glycerin solution of their toxins. The remedy was administered per os. Some very encouraging results were reported, including some apparent cures. A point much insisted on by Dr. McCourt and worthy attention of other investigators is that the remedy used should represent the toxins, not only of the neoplasm but of other complicating affections, such as syphilis, tuberculosis, etc.

At the time when Dr. McCourt began his work, the immunity theory was not distinctly worked out, so that his work appears to us somewhat crude, but it seems to have been along much the same lines as the later work and deserves attention, not only as a matter of historical interest but possibly also because it may be fruitful in suggestion to other investigators. Through former acquaintance with the doctor I am able to send you reprints of his articles on this subject published in the *Medical Review of Reviews*, November, 1899, February, 1900, and April, 1904. I believe these articles are worthy of study by those who are interested in this line of work.

J. W. Wallheim, M.D., New York.

Comments on Dr. Pettey's Article Criticizing the Lambert Treatment for Drug Addictions

To the Editor:—It would appear from a casual reading of Dr. Pettey's article (The Journal, May 14, 1910, p. 1593) that his method of procedure in treating drug addictions is radically opposed to that set forth by Dr. Alexander Lambert (The Journal, Sept. 25, 1909, p. 985). As a matter of fact, the underlying principle and purpose in both treatments are the same. Dr. Pettey's article, on careful analysis, reads not unlike a document designed to explain the various steps followed in the Lambert method.

Dr. Pettey lays stress on the fact that he administers the purgatives so that they may act at a time when the paralyzing effect on peristalsis, of the narcotic to which the patient is addicted, is at a minimum. That is, he takes advantage of the habitué's customary absence from his drug during his sleeping hours; when, naturally, peristalsis is being reestablished. Precisely this idea is adhered to in the treatment advocated by Dr. Lambert. The latter waits fourteen hours from the time he administers the narcotic before beginning active purgation; and further narcotics are not administered until this is obtained. Dr. Pettey, too, insists that the narcotic must not be given again until the bowels have been thoroughly emptied. Thus it is seen that in each case cathartic activity coincides with the fag-end of narcosis. Dr. Pettey decries the drastic cathartics employed by Dr. Lambert and then proceeds to advise a dosage which does not appear to me less heroic when we consider the powerful check the belladonna exerts in Dr. Lambert's plan. Moreover, in the cases in which I have used the Lambert method, the catharsis has not been more than was needed for successful elimination and has seemed secure from dangerous purgation. It must be borne in mind, too, that Dr. Pettey is outlining a course of treatment for a patient taking not more than 10 grains of morphin daily, while Dr. Lambert's treatment embraces the maximum amount of narcotic that may be taken.

Dr. Pettey aims to get the same results by the use of the alkaloids, atropin and scopolamin, which are obtained by Dr. Lambert from the belladonna and hyocyamus from which the alkaloids are derived. In the one, the administration is hypodermatic; in the other, by mouth. There are objections to both as a routine practice and virtue in either where indicated. Dr. Pettey rightly objects to the use of the term "specific" as applied to the combination used by Dr. Lambert. The most that can be said for the drugs in this combination is that they are antidotal. But I cannot agree with Dr. Pettey when he says that the prickly ash has no value in the treatment. This drug is a stomachic and intestinal stimulant and certainly gives the stomach greater tolerance for the other drugs used.

In both treatments characteristic bilious stools are sought for. Dr. Lambert says that "the castor oil will produce a characteristic stool composed of mucus and bile 'after which' the patient is relaxed and comfortable." Dr. Pettey states that the hyposulphite causes the "patient to have small bilious stools which prepare him for a rapid convalescence." Now, to that part of Dr. Lambert's article concerning this phase of the treatment Dr. Pettey gives this critical interpretation: that the patient reaches a "state of placidity and comfort" because he has had a liquid green stool composed of mucus and bile. I believe, however, that anyone will see from a careful reading of the two articles that the significance attached to this stool is identical in the minds of the two men. Each considers it merely as an evidence that the "hyperesthetic state" has terminated and effective elimination taken place.

Dr. Pettey has failed to call attention to a noticeable omission in the Lambert paper. While the method for treating alcoholics is carefully outlined, yet in the appended table of cases, the physician endeavoring to apply the formula finds not a case of alcoholism recorded. Then, too, Dr. Lambert's article seems to say that the treatment for a morphinist may cease at a specified time—the "characteristic stool shows that the entire treatment may cease." Yet a study of the appended table shows that in the majority of cases the so-called "specific" was continued for longer or shorter periods after the time at which, judging from the treatment outlined, it might have been stopped. In my own cases, I have found it necessary to continue the "specific" in most cases for a somewhat longer time than Dr. Lambert designates.

While it is necessary often, as Dr. Pettey suggests, to detain patients in the sanitarium for a convalescence of "one or two months," I believe that patients are sometimes harmed by over-careful carrying along. I have obtained excellent results by dismissing patients from my sanitarium just as soon as it seems at all advisable, and letting them feel that they must rely on their own strength. In most cases, however, I find it best to have patients return to my office at intervals until I am confident that their self-reliance is fully reestablished.

C. C. Wholey, Pittsburg, Pa.

Marriages

Charles J. Wehr, M.D., to Miss Lena Hitzelberger, both of Bellevue, Ohio, June 18.

Alexander J. Rooney, M.D., to Miss Sophia Livermore, both of Brooklyn, June 21.

Kinchen R. Taylor, M.D., to Mrs. Rosina C. Morton, both of New York City, June 19.

John H. Thompson, M.D., to Miss Mabel Ayers, both of Greenspring, Ohio, June 22.

H. Seth Anderton, M.D., Diboll, Tex., to Miss Margery J. Smith, at Baltimore, June 24.

Frederick George Dyas, M.D., Chicago, to Miss Mabel Freer, of Hinsdale, Ill., June 29.

Jacob John Kocher, M.D., to Miss Clareta Margaret Hicks, both of San Jose, Cal., June 15.

John B. Walker, M.D., to Miss Mai Elmendorf Hackstaff, both of New York City, June 22.

Noel Gano Mussey, M.D., Glendale, Ohio, to Miss Penelope Lever, of Loveland, Ohio, June 16.

Julius B. Evans, M.D., and Mary L. Evans, M.D., both of Ada, Ohio, at Columbus, June 20.

Leslie W. Morsman, M.D., Omaha, to Mrs. Margaret M. Thurwood, of Vail, Iowa, June 16.

Charles N. Sturdevant, M.D., Detroit, to Miss Katharine Irvine, at Mercersburg, Pa., June 18.

J. Raymond Kirk, M.D., Paw Paw, W. Va., to Miss Mary Arnold, at Springfield, W. Va., June 18.

Arthur George Blakeslee, M.D., to Miss Helen Catherine Monroe, both of New York City, June 22.

Walter Green Evans, M.D., Stuart, Okla., to Miss Hilda Abernethy Grayson, of Mobile, Ala., June 15.

Gustavus Golseth, M.D., Jamestown, N. Dak., to Miss Florence Pugh, of Casselton, N. Dak., June 14.

Elwin Carl Schneider, M.D., Washington, D. C., to Miss Celina Cruett King, at Alexandria, Va., June 21.

John Peter Schneble, M.D., Woodhaven, N. Y., to Miss Ida Brandenstein, of Glendale, Brooklyn, June 15.

Deaths

Dwight Robbins Burrell, M.D. University of Michigan, Department of Medicine and Surgery, Ann Arbor, 1868; a member of the Medical Society of the State of New York, American Medico-Psychological Association, Rochester Pathological Society, and Rochester Academy of Medicine; resident physician at Brigham Hall; one of the incorporators of the Ferris Thompson Memorial Hospital, Canandaigua; a veteran of the Civil War; died at his home in Canandaigua, June 18, from cerebral hemorrhage, aged 67.

Alfred Wanstall, M.D. New York Homeopathic Medical College and Hospital, New York City, 1875; a member of the American Medical Association; of Baltimore; aurist and physician in charge of the Baltimore Homeopathic Free Dispensary; a member of the staff of the Atlantic Medical College, Baltimore: died at Baltimore, recently, from heart disease, aged 58.

Arthur Ludwig Anderson, M.D. University of Michigan, Department of Medicine and Surgery, Ann Arbor, 1908; a member of the American Medical Association; health officer of Aurora, Ill.; died at the St. Charles Hospital, Aurora, June 26, as the result of complications following an operation for appendicitis some time before, aged 28.

Jesse W. Downey, M.D. University of Maryland, School of Medicine, Baltimore, 1869; a member of the Medical and Chirurgical Faculty of Maryland: a Confederate veteran; for many years surgeon of the First Regiment, Maryland National Guard; died at his home in New Market, June 25, from cerebral hemorrhage, aged 62.

Willis Sidney Anderson, M.D. College of Physicians and Surgeons, New York City, 1891; a member of the American Medical Association; of Detroit, Mich.; in charge of the eye and ear department at Harper Hospital for twenty years; was drowned near Belle Isle, June 27, by the capsizing of his canoe, aged 42.

Orin A. Lyon, M.D. Homeopathic Hospital College, Cleveland, 1881; a member of the Northeastern Medical Society; of Akron, Ohio: died June 17, from internal injuries caused by being crushed between his automobile and a tree while cranking the automobile a few days before, aged 55.

Henry Stanley Warren, M.D. Harvard Medical School, Boston, 1900; a member of the American Medical Association; for two years house surgeon at the Boston Children's Hospital; died at the Massachusetts General Hospital in that city, June 25, from cerebral hemorrhage, aged 36.

Clifford Harvey Robinson, M.D. Western Pennsylvania Medical College, Pittsburg, 1900: of Pittsburg; died at the home of his mother in that city, June 26, following an attack of pleurisy last December from which he had never fully recovered, aged 33.

Charles Larkin McCracken, M.D. University of Toronto, Ont., 1881; a member of the Medical Society of the State of California; tax collector of San Mateo county, California; died at his home in Redwood City, June 24, from heart disease, aged 48.

Herman D. Marcus, M.D. Medico-Chirurgical College of Philadelphia, 1891; a member of the American Medical Association; is said to have committed suicide at his home in Atlantic City, N. J., June 16, by taking a solution of cyanid of potassium.

O. T. Huebner, M.D. Hahnemann Medical College and Hospital, Philadelphia, 1869; a member of the Board of Trustees of the Millersville State Normal School; died at his home in Lancaster, Pa., June 25, from dropsy and heart disease, aged 74.

Elijah Blacksheare Bush, Jr., M.D. Atlanta (Ga.) School of Medicine, 1909; a member of the Medical Association of Georgia; surgeon to the Georgia railroad: died suddenly at his home in Colquitt, June 4, from pulmonary tuberculosis, aged 23.

Jacob Huber, M.D. Medical College of Ohio, Cincinnati, 1863; Bellevue Hospital Medical College, 1879; a member of the Illinois State Medical Society; a Civil War veteran; a former mayor and alderman of Pana, Ill.; died at that place, June 27, aged 70.

John R. Shannon, M. D. Southern Medical College, Atlanta, Ga., 1893; a member of the Medical Association of Georgia; at one time president of the Sixth Congressional District Medical Association; died at his home in Cabaniss, near Juliette, Ga., June 22.

Charles L. Gates (exemption certificate; license, 1883); one of the earliest settlers of Hancock, Minn., and a resident of that place for thirty years; was killed while walking on the Great Northern track near Hancock, June 19, aged about 75.

James Eloi Hickley, M.D. Baltimore Medical College, 1903; a member of the Massachusetts Medical Society and American Academy of Medicine: of Springfield, Mass.; died in that city, Dec. 4, 1909, from pulmonary tuberculosis, aged 31.

Belle M. Walrath, M.D. Northwestern University Woman's Medical School, Chicago, 1882; a member of the American Medical Association; of St. Paul, Minn.; died in St. Luke's Hospital, St. Paul, June 20, from cancer, aged 62.

William J. Whittaker, M. D. Royal College of Surgery, Dublin, Ireland, 1863; King's and Queen's College of Physicians, Dublin, 1864; a retired physician of Kansas City, Mo.; died at his home in that city, June 22, aged 69.

Albert Osborn Bogert, M.D. College of Physicians and Surgeons, New York City, 1875; a member of the Medical Society of the State of New York: died suddenly at his home in Spring Valley, N. Y., June 25, aged 59.

C. H. O. Young, M.D. College of Physicians and Surgeons, Baltimore, 1875; a member of the Kentucky State Medical Association; a practitioner of Flippin, Ky., for forty years; died at that place, April 22, aged 64.

George W. Cox, M.D. College of Physicians and Surgeons, Keokuk, Iowa, 1865; formerly of Clayton, Ill.; died at the Masonic Home at Sullivan, Ill., June 16, where he had lived for the past three years, aged 49.

Stephen Frost Horton, M.D. New York University Medical College, New York City, 1886; a member of the Medical Society of the State of New York; died at his home in Peekskill, N. Y., June 22, aged 45.

Harvey S. Seymour, M.D. Chicago Homeopathic Medical College, 1883; of Sugar Grove, Ill.; a veteran of the Civil War; died at the Aurora, (Ill.) Hospital, June 23, from pernicious anemia, aged 66.

William Black Rowland Jordan, M.D. College of Physicians and Surgeons, Baltimore, 1886; died at his home in Liberty Grove, Md., June 8, from ischiorectal abscess, aged 50.

Isaac D. Moore, M.D. Medical College of Georgia, Augusta, 1856; of White plains, Ga.; a surgeon during the Civil War; died at his home, June 16, from paralysis, aged 81.

William M. Hendrickson, M.D. Albany (N. Y.) Medical College, 1863; a prominent physician of Coupeville, Wash.; died at that place, May 30, from nephritis, aged 68.

John Colby Landon, M.D. Detroit (Mich.) College of Medicine, 1896; of Philadelphia, Pa.; died in that city, June 20, from heart disease, aged 40.

Emmett C. King, M.D. New York Homeopathic Medical College and Hospital, 1880; died at his home in Hartford, Conn., June 17, aged 58.

James M. Massie, M.D. Physio-Medical College of Indiana, Indianapolis, 1889; of Fort Worth, Texas; died June 15, from nephritis.

Lucius M. Quinn (license, Miss.); died at Holmesville, Miss., Nov. 5, 1909, from hepatic abscess, aged 62.

Pharmacology

DIABETOL

A Diabetes Cure of the "Tropical Herb" Type

Bearing in mind that the nostrum exploiter finds his most fertile field in the "treatment" of those diseases which kill slowly, it is not surprising to find many fake specifics on the market for the cure of diabetes. The average victim of this disease rebels at the only treatment which holds out any hope of success—careful dieting and strict attention to hygiene—and demands of the physician the impossible: a drug that is specific for his ailment. Those who treat diabetics know how terribly difficult it is to get these patients to obey the orders as to diet, etc., and how extremely prone such unfortunates are to experiment with the thousand-and-one "cures" recommended to them by well-meaning friends or by the manufacturers. The field is thus a rich one for the nostrum exploiter and needless to say is being assiduously tilled.

"Diabetol" is put on the market by the Ames Chemical Company, Whitney's Point, N. Y., and is heralded through the newspapers as "A New Discovery for the Cure of Diabetes and Kidney Diseases." The "discovery" was made, we are told, by Frank M. Ames, a civil engineer, who spent more than twenty years in tropical American countries, most of the time being in "tropical jungles." From an "absolutely reliable" native Mr. Ames learned of the existence of a "herb that would cure diabetes," and from experiments which he has made with this "herbal remedy" he finds that it "has a direct specific action in the cure of this dreaded disease."

In the advertising pamphlet the physician is told that "diabetol is not a patent or secret medicine." How much reliance can be placed on this statement may be seen by the following reply from the Ames Chemical Company to a physician who, on the strength of the above claim, wrote for information regarding this nostrum:

> "We have received your favor and would say in regard to our herb, that we do not know whether it has been classified botanically or not, as we only know the Indian name and location where it grows, which of course *we have to keep secret* [Italics ours.—ED.] to protect ourselves."
>
> "Diabetol herb will certainly cure diabetes and do it quick. . . ."

The old scheme of a "home-made" uranalysis, by which the patient may confidently be expected to frighten himself into purchasing the nostrum, is worked as follows:

> "Set aside a quantity of your morning urine for twenty-four hours, then if found cloudy, stringy or with sediment there is something wrong and you should take a few packages of Diabetol to correct your system, thereby eliminating the invasion of Diabetes or Bright's Disease."

It is hardly necessary to say that this "test" will indicate the presence of incipient diabetes or Bright's disease in no small portion of the human race.

On an advertising circular headed, "First week results with Diabetol," the following statements are made:

> "Diabetol acts like magic in the cure of diabetes and the patient improves rapidly from the first dose. Note a few of the marvelous results. Can any other remedy approximate it? We challenge comparison."

Then follows a list of individuals who enthusiastically endorse Diabetol. The worldly-wisdom of the exploiter of Diabetol in publishing "first week results" instead of later reports, was made evident when we began to receive letters from physicians to whom we had written for further information, regarding these cases. For instance:

WHAT THE TESTIMONIALS SAY	WHAT PHYSICIANS WRITE
"Have gained 5 pounds in 12 days and specific gravity lowered 13 points with a slight reduction in sugar; guess I am on the right track at last."—N. C. B., Mich.	"Relative to the matter of Mr. N. C. B.; he died May 29, 1909, from diabetic coma."
"The trial treatment has improved me a great deal and I hope to find a permanent cure in your remedy."—F. P. R., Tenn.	"Mr. F. P. R. gave Diabetol a good trial but be received no benefit from it; died about 3 weeks ago."
"I received good results from sample."—A. M. G., Pa.	"Regarding Mr. A. M. G., have conferred with both the chief of police and postmaster and am unable to locate a party having this name."
"I received your sample package of Diabctol and I think it will do all you claim."—W. E. L., Ohio.	"Mrs. W. E. L. . . . has progressively lost weight from 175 to 144 pounds. . . . She estimates the quantity of urine each 24 hours to more than fill a 12-quart pail. . . . I have to-day examined a sample of her urine and find the sp. gr. 1.034 with plenty of sugar."
"Have taken about one-half of the trial package you sent me and feel much improved already."—E. N. T., New York.	"Mr. E. N. T.'s appearance is now very good . . . says he is still weak; he tells me that *when he adheres closely to diet* and takes the medicine he feels much better . . ."
"Received sample, and it has made a big improvement in me."—G. W. Y., Md.	"Mr. G. W. Y. died Jan. —, 1910."
"I am feeling much better."—H. R., Ind.	"The party referred to . . . never had diabetes . . ."
"The sample package sent me has proved more than satisfactory."—A. P. B., New York.	"Mr. A. P. B. has had diabetes over 10 years . . . his condition is about the same as usual. . . . He now knows Diabetol did him no good."
"I have been using your herb for diabetes for four weeks with success. . . . After another package I expect very little trace of sugar in my system."—J. N. H., Iowa.	"Mr. J. N. H. had diabetes and still has. . . . He stated to the Diabetol company that he felt a little better . . . but he soon felt the same as before. I tested his urine and found it loaded with sugar."

To determine so far as possible what the nature of this marvelous "tropical herb" is, the help of Prof. C. F. Millspaugh was sought. Professor Millspaugh is curator of the department of botany of the Field Museum, Chicago, an institution having one of the most extensive collections in botany extant, and enabling the experts there to determine the character and source of almost anything that belongs to the plant world. Professor Millspaugh's reports:

ANALYSIS

"I have this day examined the contents of a package of Diabetol Herb received from you in original and unbroken package. The package contains broken young stems and leaves with a few flower buds and bits of developed flowers intermixed. All the material is from a shrub belonging to the Bignonia family and known as *Stenolobium stans* (L.) Don. *(Bignonia stans* Linn.; *Tecoma stans* Juss.) This shrub grown more or less plentifully from Arizona southward through Mexico and Central America to the northern part of South America, throughout the West Indies and to the Bahamas and south Florida. The contents of the package suggests to me that its source was somewhere near the State of Hidalgo, Mexico.

"This shrub has more or less local reputation as a diuretic and is used to some extent for that purpose by the natives of the regions in which it grows."

Diabetol, then, differs not at all from other nostrums of its class. The mysterious secret herb, the absurdly broad claims, the worthless testimonials, the exploiter without medical knowledge—all these elements enter into so many of the widely advertised "sure cures" that one would think that the very lack of originality would make their sale impossible. But there is no limit to the credulity of the hopelessly ill and on this weakness the great American fraud thrives.

CALCIUM CHLORHYDROPHOSPHATE

C. R. Noyes, pharmacist, St. Paul, Minn., calls attention to the formula on page 152 of the National Formulary, which he thinks of interest, in view of the article on calcium chlorophosphate in THE JOURNAL, May 7, 1910, page 1560.

The formula referred to is for "syrupus calcii chlorhydrophosphatis," or syrup of calcium chlorhydrophosphate. In the preparation of this syrup calcium phosphate is dissolved by the addition of hydrochloric acid. It therefore does not contain the hypothetical or impossible compound indicated by its title, but instead appears to owe its therapeutic value to calcium acid phosphate and calcium chlorid. Thus THE JOURNAL'S criticism of Pautauberge's solution, to the effect that it is claimed to contain a chemical substance unknown to chemists, may with equal fairness be applied to the National Formulary preparation referred to. The assertion has been made that a number of the preparations in the National Formulary have been devised in imitation of, or rather as substitutes for, certain proprietary mixtures which had become somewhat popular. This assertion derives a certain degree of support by a comparison of the two preparations in question. In naming the preparation, it is probable that the makers of the formulary were guided by the composition claimed for Pautauberge's solution, although they should have known there is no such substance as calcium chlorhydrophosphate.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

MUNICIPAL HOSPITALS

To the Editor:—Are there any municipal hospitals built on the plan of providing a room for each patient? Two or three years ago you had some plans in THE JOURNAL, which I put away, but have lost. Please refer me to them. T. D. LONGINO, Atlanta, Ga.

ANSWER.—So far as we know there is no municipal hospital in which each patient has a private room. There are private rooms in nearly all municipal hospitals for certain classes of patients, such as the insane, some of the infectious diseases, and so on. In a number of children's hospitals, and in general hospitals that have children's departments, there are what are known as observation wards; these are private rooms fitted with private bath, basin and toilet, so that a child suffering from one of the exanthemata, or suspected of developing a contagion or infection, can be isolated until the disease develops. These rooms are built with part of the partitions of glass, with the head nurse's desk so placed that she can look through two or three, or even more of these private rooms.

Nearly all detention hospitals which are municipal in character, and supported by the public are made up of a private room for each patient, and a common recreation room where a single guard can watch a number of patients as they exercise or associate with each other. The tendency, however, is to construct hospitals generally with wards very much smaller, containing say a maximum of ten or fifteen beds. Nearly all municipal hospitals are now constructed with one or more so-called "quiet rooms" off each ward, in which special cases may be placed, as for instance, immediately following operations, delirious patients, patients that are noisy, patients suffering from some nervous affection, making them oversensitive to noises made by others.

SERUM FOR EXOPHTHALMIC GOITER

To the Editor:—Please inform me where Rogers' serum for the treatment of goiter can be obtained; also give brief comment as to its usage. S. W. T.

ANSWER.—The antithyroid serum for use in exophthalmic goiter or Graves' disease can be obtained on application to Dr. S. P. Beebe, at the Loomis Laboratory, 414 East Twenty-sixth Street, New York City. It will be furnished only after receiving complete information in regard to the particular case under treatment. It is of therapeutic value only in cases of so-called exophthalmic goiter. It is of no value in the type known as "simple goiter." The antithyroid serum is not harmless and cannot be administered with impunity on the principle that if a little is good, more is better. The dosage must be carefully regulated to suit the condition of the patient. The injections are rarely given oftener than once in twenty-four hours and are not to be continued in the face of manifest increasing severity of reaction. The serum treatment, with its modifications, has been discussed in the November, 1908, number of the *Archives of Internal Medicine* and in the *Annals of Surgery*, December, 1909, and February, 1910. As the serum is not on a commercial basis, and as it is prepared at large expense by the Cornell University Medical College, in which the Loomis Laboratory is devoted to the department of experimental therapeutics, the laboratory should be asked to supply it only in cases in which it is really indicated, and therefore careful case records should be furnished with all requests for the serum. These records of cases are preserved for reference.

The Public Service

Medical Department, U. S. Army

Changes for the week ended July 2, 1910:

Nichols, Henry J., capt., granted 3 months' leave of absence, with permission to go beyond sea, about July 1, 1910.

Allen, John H., major, left Fort Meyer, Va., accompaning Headquarters Band and Troops A, B and D, 15th Cavalry, en route to Camp of Instruction, Gettysburg, Pa.

Waterhouse, S. M., major, left Fort Washington, Md., en route to Washington Barracks, D. C., for duty with Headquarters, and Cos. A and D, 1st Batt. Engineers, to Camp of Instruction at Gettysburg, Pa.

Sheep, William J., lieut., left Fort Myer, Pa., accompanying Headquarters 2nd Battalion and Batteries E and F, 3rd Field Artillery, to Camp of Instruction, Gettysburg, Pa.

Casaday, George H., dental surgeon, ordered to proceed to Fort Baker, Cal., for temporary duty.

Reno, W. W., major, left Fort McKinley, Me., en route to South Framingham, Mass., for duty as inspector-instructor to Ambulance Co. and Hospital Co. Massachusetts Militia.

Hollingsworth, R. M., dental surgeon, contract annulled June 20, 1910.

Ingalls, R. E., dental surgeon, left Fort Douglas, en route to Fort Duchesne, Utah, for temporary duty.

Talbott, E. M., capt., and Haverkampf, G. W., lieut., left Fort D. A. Russell, Wyo., with Co. A, Hospital Corps, en route to military tournament, Chicago.

Williams, H. B., M. R. C., left Camp Upton, Sparta, Wis., en route to military tournament Chicago.

Cosman, George H. R., major, left Fort Barrancas, Fla., en route to Chickamauga Park, Ga., for duty at Camp of Instruction.

[illegible] A., capt., and Bastion, J. E., lieut., left Walter Reed General Hospital, Takoma Park, D. C., with detachment of Hospital Corps Co. C, en route to Camp of Instruction, Gettysburg, Pa.

Taylor, Blair D., col., left Atlanta, Ga., for duty as Chief Surgeon, Camp of Instruction, Chickamauga Park, Ga.

Reynolds, Frederick P., major, ordered to proceed from Fort Monroe, Va., to Kavner, N. Y., and report on arrival to the senior instructor at the encampment of infantry officers, 3rd Brigade, State of New York, for duty delivering lectures on camp sanitary, etc.

Appel, Aaron, H., col., detailed as Chief Surgeon of Camp of Instruction at the Fort D. A. Russell Target and Maneuver Reservation, Wyo.

Ingalls, Raymond E., dental surgeon, ordered from Fort Douglas, Utah, to Fort Duchesne, Utah, thence to Fort Wingate, N. Mex., for such professional services as may be required of him at those posts.

Shook, Jay R., major, ordered to Denver to take physical test.

Marietta, Shelley U., M. R. C., with one sergeant and one private first class or private H. C., with one ambulance and necessary medical supplies, ordered from Fort Des Moines, Iowa, by marching, to Iowa City, Iowa, to participate in encampment of 54th Iowa Inf., from July 18 to 27.

Morgan, Norman D., contract surgeon, relieved from duty at Presidio of San Francisco, June 30, and ordered to report to Chief Surgeon of that Department for annulment of contract.

Lowe, Thomas S., M. R. C., ordered from Presidio of Monterey, Cal., to Atascadero, Cal., for temporary duty, relieving Contract Surgeon James W. Brownlie, Jr., who is directed to report to Chief Surgeon of Department on June 30, for annulment of contract.

Johnson, Thomas H., M. R. C., ordered from Fort Baker to Fort Mason, Cal., for temporary duty as post surgeon and attending surgeon Headquarters Department of California, during illness of Captain Perry L. Boyer, Medical Corps, or until latter is relieved.

Hill, Eben C., 1st lieut., sick leave of absence further extended 1 month.

Carr, William B., 1st lieut., detailed member of examining board at Fort Monroe, Va., vice Captain George P. Peed, M. C., relieved.

Sharpe, Herbert H., M. R. C., assigned to permanent duty at Fort Niagara.

Bartlett, Cosam J., capt., ordered to Fort Banks, Mass., as member of examining board to meet July 12, 1910.

Crum, Wayne H., M. R. C., ordered to Fort Ontario, N. Y., as member of examining board to meet July 12, 1910.

Patterson, Robert F., dental surgeon, ordered from San Francisco to Fort Sheridan, Ill., for duty.

Johnson, Howard H., capt., granted 2 months' leave of absence, to take effect on or about July 20, 1910.

Myers, William H., M. R. C., ordered to Fort Screven, Ga., for duty, relieving First Lieutenant Fred T. Koyle, M. R. C., who is ordered to Fort Mansfield, R. I., for duty, on expiration of leave.

Sanford, Joseph L., M. R. C., granted leave of absence for 4 days to take effect on or about July 5, 1910.

Oliver, Robert T., examining and supervising dental surgeon, granted 2 months' leave of absence, to take effect on or about July 1, 1910.

Siler, Joseph F., capt., ordered from New York City to Peoria, Ill., to study pellagra in connection with commission organized by the governor of Illinois.

Blanchard, R. M., capt., reported for duty at Camp J. M. Dickinson, Chicago.

Person, Elbert E., major, reported for duty at Camp of Instruction, Gettysburg, Pa.

Woodall, William P., capt., reported for duty to temporary command of one-half of Co. A, Hospital Corps, at Target and Maneuver Camps at Fort D. A. Russell, Wyo.

Oliver, Robert T., E. S. D. S., order to proceed to Camp of Instruction at Gettysburg, Pa., is revoked.

Hallett, Harley J., M. R. C., relieved from temporary duty at Fort Hamilton, N. Y., and ordered to return to Fort Totten, N. Y.

Hartnett, E. H., major, ordered to Fort Monroe, Va., for temporary duty.

Talbott, E. M., capt., and Haverkampf, C. W., lieut., report arrival at Camp J. M. Dickinson, Chicago, for duty.

Demmer, C. C., lieut., left Fort Thomas, Ky., for duty at Camp of Instruction, Gettysburg, Pa.

Johnson, Thomas H., M. R. C., reported for temporary duty at Fort Mason, Cal., and as attending surgeon, Department Headquarters.

Beery, Harry R., lieut., reported for duty at Camp J. M. Dickinson, Chicago.

Williams, H. B., M. R. C., reported for duty at Camp J. M. Dickinson, Chicago.

Owen, L. J., capt., left Fort Benjamin Harrison, Ind., en route to Camp J. M. Dickinson, Chicago.

Lynch, Edward C., M. R. C., left Omaha, en route to take station at Fort D. A. Russell, Wyo.

U. S. Public Health and Marine-Hospital Service

Changes for the week ended June 29, 1910:

Irwin, Fairfax, surgeon, leave of absence for 1 month and 10 days from Sept. 1, 1910, amended to read from September 15.

Banks, Charles E., surgeon, leave of absence granted for 12 days from June 12, 1910, amended to read 10 days from June 15, 1910.

Wasdin, Eugene, surgeon, granted 1 month's leave of absence from June 22, 1910, on account of sickness.

Brooks, S. D., surgeon, detailed to represent the Service at the meeting of the American Institute of Homeopathy to be held in Los Angeles, Cal., July 11-15, 1910.

Cobb, J. O., surgeon, granted 7 days' leave of absence from June 26, 1910.

Geddings, H. D., surgeon, detailed to attend the First International Congress of Administrative Sciences to be held at Brussels, Belgium, July 28-31, 1910.

Von Ezdorf, R. H., P. A. surgeon, granted 5 days' leave of absence from June 28, 1910, on account of sickness.

Lumsden, L. L., P. A. surgeon, reassigned for duty in the Hygienic Laboratory, effective June 27, 1910.

Holt, John M., P. A. surgeon, granted 7 days' leave of absence June 19, 1910, and 1 day's leave of absence June 26, 1910.

Lloyd, B. J., P. A. surgeon, granted 1 month's leave of absence from June 20, 1910, on account of sickness.

Bahrenburg, L. P. H., P. A. surgeon, granted 18 days' leave of absence from July 1, 1910.

Warren, B. S., P. A. surgeon, granted 2 months' leave of absence from July 5, 1910.

Stimson, A. M., P. A. surgeon, reassigned for duty in the Hygienic Laboratory, effective June 29, 1910.

Spratt, R. D., P. A. surgeon, granted 7 days' leave of absence from June 14, 1910, on account of sickness.

Herring, R. A., asst.-surgeon, granted 14 days' leave of absence from June 15, 1910.

Adams, X. F. B., acting asst.-surgeon, granted 4 days' leave of absence from June 30, 1910.

Duncan, W. A., acting asst.-surgeon, granted 28 days' leave of absence with pay, and 2 days' leave of absence without pay from May 5, 1910.

Fahey, B. W., acting asst.-surgeon, granted 7 days' leave of absence from June 24, 1910.

Parker, Thomas F., acting asst.-surgeon, granted 4 months' leave of absence without pay from July 1, 1910.

Stanton, J. C., acting asst.-surgeon, granted 4 days' leave of absence from June 27, 1910.

Weldon, William A., acting asst.-surgeon, granted 30 days' leave of absence from July 5, 1910.

Wilson, J. G., acting asst.-surgeon, granted 7 days' leave of absence from June 22, 1910, under paragraph 210, Service Regulations.

Association News

NEW MEMBERS

The following is a list of new members of the American Medical Association for the month of June, 1910. Stars and daggers are placed before those who became members at the St. Louis Session; the dagger indicates that the name so marked was previously on the subscription list.

ALABAMA

*Blake, W. H., Sheffield.
*Copeland, M. A., Birmingham.
†Goode, Rhett, Mobile.
Peterson, E. A., Mobile.
†Stubbins, S. G., Birmingham.

ARKANSAS

*Biles, Lee E., Augusta.
*Bourland, O. M., VanBuren.
Davis, E. N., Little Rock.
Harrison, F. E., Fordyce.
*Lightfoot, J. A., Texarkana.
*Neece, Thos. C., Walnut Ridge.
†Powell, J. T., Maysville.
Purifoy, L. L., El Dorado.
*Reeves, W. R., Alma.
Rodman, T. N., Cushman.
*Watson, E. L., Newport.
Webb, Abner, Ft. Smith.

CALIFORNIA

Bunnell, Sterling, San Francisco.
Bruman, A. K., San Francisco.
O'Neill, B. J., San Diego.
†Sellery, A. C., Long Beach.

COLORADO

Davis, J. B., Denver.
†Elliott, E. W., Ft. Morgan.
*Neuman, D. S., Denver.

CONNECTICUT

†Hepburn, T. N., Hartford.

FLORIDA

Thompson, J. M., Ocala.

GEORGIA

Adair, Robin, Atlanta.
Bradley, T. E., Cordele.
Dennard, J. H., East Point.
Moore, J. M., Macon.
Murray, G. S., Columbus.
Roberts, C. W., Douglas.
Stuckey, E. O., Atlanta.

ILLINOIS

*Adams, J. W., Carrollton.
†Allyn, W. H., Waverly.
†Altman, Maurice, Springfield.
*Beard, I. J., Godfrey.
*Berrey, I. S., Batchtown.
†Bradley, R. C., Peoria.
Brown, L. S., Hillsboro.
*Bryant, J. B., Lawrenceville.
*Burke, C. O., Atlanta.
†Cannady, E. W., E. St. Louis.
†Carter, Wm. J., Mattoon.
*Caseburn, A. L., Ferris.
Casey, L. B., Marion.
*Chapin, H. A., White Hall.
†Cook, E. A., Upper Alton.
*Crain, B. F., Carterville.
Culbertson F. D., Littleton.
*Davidson, W. E., Kingston.
†Duane, J. F., Peoria.
†Du Four, W. G., Chenoa.
†Flentje, Robt., Buffalo.
*Fockler, G. W., Delavan.
Garrison, A. J., Buckley.
*Glascock, E. N., Mill Shoals.
*Gore, C. P., Lawrenceville.
†Grear, D. W., Jonesboro.
Green, W. I., Sumner.
Harrigan, C. P., Chicago.
†Hick, J. C., Eldorado.
†Nilliard, T. J., Fairfield.
*Johnson, C. W., Litchfield.
Jones, Wm., Aurora.
†King, B. H., Granite.
*King, J. A., Victoria.
†Knappenberger, T. G., Chicago.
†Lamb, J. G., Fisher.
†Lane, E. H., E. St. Louis.
*LeSaulnier, H. L., Red Bud.
*Lescher, E. R., Mt. Carmel.
Lockwood, F. K., Virden.
*Long, J. H., E. Moline.
*McKee, J. F., Johnston City.
*McMurray, R. J., St. Francisville.
*McNemer, G. H., Cairo.
Meirink, B. J., Germantown.
Niess, John, Jr., Carmi.
*Nobles, C. D., Buncombe.
†Nyberg, R. B., Harrisburg.
*Paul, E. W., Forest City.
*Perry, W. H., Carterville.
*Pope, R. D., DuQuain.
Rayhill, C. G., Belleville.
*Riffey, J. H., Girard.
Roberts, R. B., Brimfield.
Rubovits, W. H., Chicago.
Russell, Rose A., Granite City.
*Sanders, C. J., Ashley.
*Sanders, K. D., Jonesboro.
*Scott, F. C., Adrian.
*Shawl, J. L., Onarga.
*Siegel, J. H., Collinsville.
Stacy, G. H., Jacksonville.
Steffenson, O. M., Chicago.
Stiehl, E. P., Floraville.
*Stewart, J. H., Jr., Exeter.
*Summers, Edmund, Mattoon.
†Tharp, Royal, Benton.
Thomas, J. Smith, Pleasant Hill.
†Tobin, J. R., Elgin.
†Treadway, W. Y., Jacksonville.
*Trueblood, R. R., Lawrenceville.
†Turner, A. F., Taylorville.
†Van Hook, H. M., Mt. Pulaski.

State Boards of Registration

COMING EXAMINATIONS

Alabama: Montgomery, July 12. Chairman, Dr. W. H. Sanders.

Connecticut: Regular, City Hall, New Haven, July 12-13. Sec., Dr. Charles A. Tuttle; Homeopathic, New Haven, July 12. Sec., Dr. Edwin C. M. Hall, 82 Grand Ave.; Eclectic, New Haven, July 12. Sec., Dr. T. S. Hodge, 19 Main Street, Torrington.

District of Columbia: Washington, July 12-15. Sec., Dr. George C. Ober, 125 B Street, S. E.

Indiana: Room 120, State House, Indianapolis, July 12-14. Sec., Dr. W. T. Gott.

Maine: Augusta, July 19-20. Sec., Dr. F. W. Searle, Portland.

Massachusetts: State House, Boston, July 12-14. Sec., Dr. Edwin B. Harvey.

Oklahoma: Ione Hotel, Guthrie, July 12. Sec., Dr. Frank P. Davis, Enid.

South Dakota: Lead, July 13-14. Sec., Dr. F. W. Freyberg, Mitchell.

Vermont: Burlington, July 12-14. Sec., Dr. W. Scott Nay, Underhill.

West Virginia: Capitol Bldg., Charleston, July 11-13. Sec., Dr. H. A. Barbee, Point Pleasant.

Wisconsin: Madison, July 12-15. Sec., Dr. John M. Beffel, 3200 Clybourn Street, Milwaukee.

Nebraska February Report

Dr. E. Arthur Carr, secretary of the Nebraska State Board of Health, reports the written examination held at Lincoln, Feb. 9, 1910. The number of subjects examined in was 13; total number of questions asked, 130; percentage required to pass, 75. *Only one candidate, a graduate of Lincoln Medical* College, 1906, was examined, and he passed with a grade of 86.8 per cent. Twenty candidates have been licensed through reciprocity since Jan. 1, 1910. The following colleges were represented:

LICENSED THROUGH RECIPROCITY

College	Year Grad.	Reciprocity with.
Denver Homeopathic College	(1906)	Colorado
Northwestern University Medical School	(2, 1908)	Illinois
College of Physicians and Surgeons, Chicago (1905) (1906)	(1907)	Illinois
Jenner Medical College	(1909)	Illinois
Rush Medical College	(1886)	Indiana
Bennett Medical College	(1908)	Missouri
Keokuk Medical College	(2, 1895)	Iowa
Keokuk Med. Coll., Coll. of Phys. and Surgs.	(1906)	Iowa
University of Michigan, College of Medicine	(1909)	Missouri
Tufts College Medical School	(1907)	Maine
Barnes University	(1903) (1906)	Missouri
St. Louis College of Physicians and Surgeons	(1899)	Missouri
Creighton Medical College	(1909)	Iowa
University of Vermont, College of Medicine	(1898)	Vermont
Royal University, Paria, Italy	(1890)	Kansas

Florida April Report

Dr. J. D. Fernandez, secretary of the Florida State Board of Medical Examiners, reports the written examination held at Jacksonville, April 2-5, 1910. The number of subjects examined in was 7; total number of questions asked, 70; percentage required to pass, 75. The total number of candidates examined was 38, of whom 32 passed and 6 failed. The following colleges were represented:

PASSED

College	Year Grad.	Per Cent.
University of Alabama	(1909)	85.2
University of Arkansas	(1908)	83
Howard University	(1907)	93
Atlanta College of Physicians and Surgeons	(1907) (1908) (1909)	75 75 75
Medical College of Georgia	(1892)	75
Rush Medical College	(1893)	80.8
Chicago Medical College	(1875)	75
College of P. & S., Indianapolis	(1883)	75
University of Iowa, College of Medicine	(1881)	76.8
University of Maryland	(1909)	85.2
Harvard Medical School	(1906)	92.2
Barnes Medical College	(1896)	75.6
Albany Medical College	(1892)	82
Columbia University, College of P. & S.	(1889)	79.5
North Carolina Medical College	(1908)	92.1
Miami Medical College	(1874)	75
University of Pennsylvania	(1895) (1896)	77.2 75
Jefferson Medical College	(1902) (1906)	81.7 91.2
Vanderbilt University	(1905)	86.5
University of the South	(1907)	78.7
University of Tennessee	(1909)	80.5
Memphis Hospital Medical College	(1908)	75
Medical College of the State of South Carolina	(1881) (1909)	75 82, 84.7
University of Vermont	(1892)	75
University of Munich, Germany	(1878)	85.5
University of Havanna, Cuba	(1908)	77.3

FAILED

College	Year Grad.	Per Cent.
Georgia College of Eclectic Medicine and Surgery	(1891)	47.7
Atlanta College of Physicians and Surgeons	(1909)	56.4
Medical College of Georgia	(1906)	64
Meharry Medical College	(1909)	67.7
Gate City Medical College	(1903)	60.8
University of Havana, Cuba	(1908)	77.3

The following questions were asked:

ANATOMY

1. What bones enter into the formation of the skull? 2. Name the bones of the hand. 3. Describe the diaphragm and name its openings. 4. Give the boundaries of scarpa's triangle and name its contents. 5. What nerves supply the tongue and give function of each? 6. Give origin, course and distribution of the left pneumogastric nerve. 7. Name the branches of the arch of the aorta. 8. Describe the pulmonary artery. *What function does it perform?* 9. Name the muscles of the abdomen. 10. Name the muscles of the orbit and give function of each.

PHYSIOLOGY

1. What is the difference between serous and synovial membranes? Name the serous membranes. 2. What is the difference between a *secretion and an excretion? Name three of each.* 3. Describe the process of breathing. How does the blood become oxygenated in the lungs? 4. Describe the mechanism of the production of the voice, and how is the pitch changed from one key to another? 5. Describe the vision. Why does the pupil dilate and contract? 6. Describe the general arrangement of the cerebrospinal axis and the functions of the white and gray matter. 7. What is the effect of the pneumogastric nerve on the heart? 8. What are the component *parts of blood and the function of each part?* 9. Describe the action and relative time of action of each of the valves of the heart. 10. How and where are carbohydrates converted, during digestion?

SURGERY

1. Give symptoms and treatment of shock. 2. What are the sources of *wound infection? 3. What are the constitutional* symptoms in severe burns, and what is the *treatment?* 4. Give treatment in case of large, irregular foreign body in the eyeball. 5. Give symptoms and treatment of chronic suppuration of the middle ear. 6. Give *diagnosis between fracture of lower end of* humerus and dislocation of forearm backward. 7. How would you reduce a sub*coracoid dislocation? 8. Give symptoms and treatment* of fracture at the base of the skull. 9. What is the most common site of fracture of the *clavicle, and how would you treat it? 10. Give symptoms* and treatment of cholelithiasis.

GYNECOLOGY

1. Give indications and contraindications for the use of the curette. 2. State under what conditions hysterectomy for cancer of the uterus is not justifiable; how determined, and give treatment in inoperable cases. 3. Give symptoms, diagnosis and differential diagnosis for submucous fibromyoma. 4. Give causes, symptoms and treatment for various forms of dysmenorrhea. 5. Differential diagnosis of ascites from ovarian cyst. 6. Describe in detail operation for complete laceration of perineum, involving rectovaginal septum. 7. Describe operation for removal of intraligamentous myoma. 8. Give description as to treatment of abscess of the cul-de-sac of *Douglas.* 9. Give symptoms of pelvic hematocele? 10. Outline symptoms of torsion of pedicle of ovarian cyst.

MATERIA MEDICA—THERAPEUTICS

1. What is incompatibility in medicine, and what are the different kinds of incompatibles? Give an example of *each.* 2. Why should you prescribe the salts of the alkaloids instead of the alkaloids themselves? 3. Mention three drugs used in the treatment of *intermittent fever. State how each* controls this disease. 4. Give the theory of the alkaline treatment of rheumatism. 5. What remedies would you employ to correct anemic *conditions, and how are they used? 6. Define* an antiseptic agent. Mention two *important intestinal* antiseptics, the diseases in which they are *indicated and explain how* they are used. 7. How should ophthalmia neonatorum be prevented and how treated? 8. In what conditions may cathartics be useful in the treatment of diarrhea or *dysentery? 9. Name some conditions in* which the bromids are indicated and state your method of giving them in large doses. 10. The dose of medicine *given by* the mouth being 1 grain, what would be the equivalent dose for hypodermic use and what for administration by the rectum?

OBSTETRICS

1. What are the boundaries *and dimensions* of the outlet of the pelvis? 2. Name the presumptive and positive signs of pregnancy. 3. Give leading points in the diet and hygiene of *pregnancy.* 4. Define ovum, *spermatozoon,* embryo, fetus, abortion. 5. On what grounds is it proper to produce an abortion? 6. What should the obstetrician's bag contain? 7. Describe the formation of the placenta and give its function. 8. If called to give evidence in a court of justice, how would you determine whether *rape had been* committed? 9. What is the *significance* of albuminuria in pregnancy? Its treatment. 10. Describe the proper treatment of a shoulder presentation.

CHEMISTRY

1. Define the terms, chemical affinity, valence, decomposition of compounds, the nascent state and basic substances. 2. Express in chemical equation the reaction resulting from the combination (in solution), of sodium carbonate and calcium chlorid. 3. Mention the properties of nitrogen. 4. What remedies are usually employed in treating an acute case of phosphorus poisoning? 5. How would you treat a case of bichlorid of mercury poisoning? 6. What are the local and constitutional symptoms of carbolic-acid poisoning? 7. Enumerate the domestic remedies used as antidotes in poisoning by caustic potash and caustic soda. 8. What is the general mode of obtaining alkaloids? 9. How do you determine the nature of a white precipitate thrown down by boiling a specimen of urine? 10. Describe the method of preparing Haine's test solution for sugar and how used.

Medical Economics

THIS DEPARTMENT EMBODIES THE SUBJECTS OF ORGANIZATION, POSTGRADUATE WORK, CONTRACT PRACTICE, INSURANCE FEES, LEGISLATION, ETC.

THE MEDICAL SECTS*

In the reconstruction just sketched no allusion has been made to medical sectarianism. We have considered the making of doctors and the increase of knowledge; allopathy, homeopathy, osteopathy, have cut no figure in the discussion. Is it essential that we should now conclude a treaty of peace, by which the reduced number of medical schools shall be so pro-rated as to recognize dissenters on an equitable basis?

The proposition raises at once the question as to whether in this era of scientific medicine, sectarian medicine is logically defensible; as to whether, while it exists, separate standards, fixed by conditions under which it can survive, are justifiable. Prior to the placing of medicine on a scientific basis sectarianism was, of course, inevitable. Every one started with some sort of preconceived notion, and from a logical point of view one preconception is as good as another. Allopathy was just as sectarian as homeopathy. Indeed, homeopathy was the inevitable retort to allopathy. If one man "believes" in dissimilars contrary suggestion is certain to provide another who will stake his life on similars; the champion of big doses will be confronted by the champion of little ones. But now that allopathy has surrendered to modern medicine, is not homeopathy borne on the same current into the same harbor?

The modern point of view may be restated as follows: Medicine is a discipline in which the effort is made to use knowledge procured in various ways in order to effect certain practical ends. With abstract general propositions it has nothing to do. It harbors no preconceptions as to diseases or their cure. Instead of starting with a finished and supposedly adequate dogma or principle it has progressively become less cock-sure and more modest. It distrusts general propositions, *a priori* explanations, grandiose and comforting generalizations. It needs theories only as convenient summaries in which a number of ascertained facts may be used tentatively to define a course of action. It makes no effort to use its discoveries to substantiate a principle formulated before the facts were even suspected. For it has learned from the previous history of human thought that men possessed of vague preconceived ideas are strongly disposed to force facts to fit, defend, or explain them. And this tendency both interferes with the free search for truth and limits the good which can be extracted from such truth as is in its despite attained.

Modern medicine has therefore as little sympathy for allopathy as for homeopathy. It simply denies outright the relevancy or value of either doctrine. It wants not dogma, but facts. It countenances no presupposition that is not common to it with all the natural sciences, with all logical thinking.

The sectarian, on the other hand, begins with his mind made up. He possesses in advance a general formula, which the particular instance is going to illustrate, verify, reaffirm, even though he may not know just how. One may be sure that facts so read will make good what is expected of them; that only that will be seen which will sustain its expected function; that every aspect noted will be dutifully loyal to the revelation in whose favor the observer is predisposed; the human mind is so constituted.

It is precisely the function of scientific method—in social life, politics, engineering, medicine—to get rid of such hindrances to clear thought and effective action. For it, comprehensive summaries are situate in the future, not in the past; we shall attain them, if at all, at the end of great travail; they are not lightly to be assumed prior to the beginning. Science believes slowly; in the absence of crucial demonstration its mien is humble, its hold is light. "One should not teach dogmas; on the contrary, every utterance must be put to the proof. One should not train disciples, but form observers; one must teach and work in the spirit of natural science."[1]

Scientific medicine therefore brushes aside all historic dogma. It gets down to details immediately. No man is asked in whose name he comes—whether that of Hahnemann, Rush, or of some more recent prophet. But all are required to undergo rigorous cross-examination. Whatsoever makes good is accepted, becomes in so far part, and organic part, of the permanent structure. To plead in advance a principle couched in pseudo-scientific language or of extra-scientific character is to violate scientific quality. There is no need, just as there is no logical justification, for the invocation of names or creeds, for the segregation from the larger body of established truth of any particular set of truths or supposed truths as especially precious. Such segregation may easily invest error with the sanctity of truth; it will certainly result in conferring disproportionate importance on the fact or procedure marked out as of pivotal significance. The tendency to build a system out of a few partially apprehended facts, deductive inference filling in the rest, has not indeed been limited to medicine, but it has nowhere else had more calamitous consequences.

The logical position of medical sectarians to-day is self-contradictory. They have practically accepted the curriculum as it has been worked out on the scientific bases. They teach pathology, bacteriology, clinical microscopy. They are thereby committed to the scientific method; for they aim to train the student to ascertain and interpret facts in the accepted scientific manner. He may even learn his sciences in the same laboratory as the non-sectarian. But scientific method cannot be limited to the first half of medical education. The same method, the same attitude of mind, must consistently permeate the entire process. The sectarian therefore in effect contradicts himself when, having pursued or having agreed to pursue the normal scientific curriculum with his students for two years, he at the beginning of the third year produces a novel principle and requires that henceforth the student effect a compromise between science and revelation.

Once granted the possibility of medical dogma, there can be no limit to the number of dissenting sects. As a matter of fact, only three or four are entitled to serious notice in an educational discussion. The chiropractics, the mechanotherapists, and several others are not medical sectarians, though exceedingly desirous of masquerading as such; they are unconscionable quacks, whose printed advertisements are tissues of exaggeration, pretense, and misrepresentation of the most unqualifiedly mercenary character. The public prosecutor and the grand jury are the proper agencies for dealing with them.

Sectarians, in the logical sense above discussed, are (1) the homeopathists, (2) the eclectics, (3) the physiomedicals, (4) the osteopaths. All of them accept in theory, at least, the same fundamental basis. They admit that anatomy, pathology, bacteriology, physiology, must form the foundation of a medical education, to use the words broadly so as to include all varieties of therapeutic procedure. They offer no alternative to pathology or physiology; there is, they concede, only one proper science of the structure of the human body, of the abnormal growths that afflict it. So far, they make no issue as against scientific medicine. Much is involved in agreement up to this point. The standards of admission to the medical school, the facilities which the schools must furnish in order effectively to teach the fundamental branches, are the same for all alike. A student of homeopathy or of osteopathy needs to be just as intelligent and mature as a student of scientific medicine; and he is no easier to teach; for during the first and second years, at least, he is supposed to be doing precisely the same things.

[1] Orth, Johannes: Berl. klin. Wchnschr., xliii, p. 818.

At the beginning of the clinical years, the sectarian interposes his special principle. But educationally, the conditions he needs thenceforth do not materially differ from those needed by consistently scientific medicine. Once more, whatever the arbitrary peculiarity of the treatment to be followed, the student cannot be trained to recognize clinical conditions, to distinguish between different clinical conditions, or to follow out a line of treatment, except in the ways previously described in dealing with scientific medicine. He must see patients and must follow their progress, so as to discover what results take place in consequence of the specific measures employed. A sectarian institution, being a school in which students are trained to do particular things, needs the same resources and facilities on the clinical side as a school of scientific medicine.

Sectarian institutions do not exist in Canada; in the United States there are 32 of them, of which 15 are homeopathic, 8 eclectic, 1 physiomedical, and 8 osteopathic. . . .

HOMEOPATHIC COLLEGES

None of the fifteen homeopathic schools[2] requires more than a high school education for entrance; only five[4] require so much. The remaining eleven got less—how much less depending on their geographic locations rather than on the school's own definition. . . .

On the laboratory side, though the homeopaths admit the soundness of the scientific position, they have taken no active part in its development. Nowhere in homeopathic institutions, with the exception of one or two departments at Boston University, is there any evidence of progressive scientific work. Even "drug proving" is rarely witnessed. The fundamental assumption of the sect is sacred; and scientific activity cannot proceed where any such interdict is responsible for the spirit of the institution. The homeopathic departments at Iowa and Michigan are in this respect only half-schools—clinical halves. For their students get their scientific instruction in pathology, anatomy, etc., in the only laboratories which the university devotes to those subjects, under men none of whom sympathize with homeopathy. Their disadvantage is increased by the fact that the instruction is adapted to students who have had one or two years of college work. The general argument in favor of higher standards is here reinforced by the consideration that the homeopathic students should certainly qualify themselves for the only grade of scientific instruction that the two universities offer.

Of complete homeopathic schools, Boston University, the New York Homeopathic College, and the Hahnemann of Philadelphia alone possess the equipment necessary for the effective routine teaching of the fundamental branches. None of them can employ full-time teachers to any considerable extent. But they possess fairly well-equipped laboratories in anatomy, pathology, bacteriology and physiology, a museum showing care and intelligence, and a decent library. Boston University deserves especial commendation for what it has accomplished with its small annual income. . . .

In respect to hospital facilities, the University of Michigan, Boston University, and the New York Homeopathic alone command an adequate supply of material, under proper control, though modern teaching methods are not thoroughly utilized even by them. The Iowa school controls a small, but inadequate, hospital. All the others are seriously handicapped by either lack of material or lack of control, and in most instances by both. . . .

The dispensary situation is rather worse. Iowa and Ann Arbor have little opportunity. Of the others, Boston University alone has a really model dispensary, comparing favorably in equipment, organization and conduct with the best institutions of the kind in the country. The New York Homeopathic, the Chicago Hahnemann, and the Philadelphia Hahnemann command material enough. The others lack material, equipment or care; in some instances they lack everything that a dispensary should possess.

Financially, the two state university departments and the New York homeopathic schools are the only homeopathic schools whose strength is greater than their fee income. All the others are dependent on tuition. Their outlook for higher entrance standards or improved teaching is, therefore, distinctly unpromising. . . .

In the year 1900 there were twenty-two homeopathic colleges in the United States; to-day there are fifteen; the total student enrolment has within the same period been cut almost in half, decreasing from 1909 to 1009[9]; the graduating classes have fallen from 413 to 246. As the country is still poorly supplied with homeopathic physicians, these figures are ominous; for the rise of legal standard must inevitably affect homeopathic practitioners. In the financial weakness of their schools, the further shrinkage of the student body will inhibit first the expansion, then the keeping up of the sect.

Logically, no other outcome is possible. The ebbing vitality of homeopathic schools is a striking demonstration of the incompatibility of science and dogma. One may begin with science and work through the entire medical curriculum consistently, exposing everything to the same sort of test; or one may begin with a dogmatic assertion and resolutely refuse to entertain anything at variance with it. But one cannot do both. One cannot simultaneously assert science and dogma; one cannot travel half the road under the former banner, in the hope of taking up the latter, too, at the middle of the march. Science, once embraced, will conquer the whole. Homeopathy has two options: one to withdraw into the isolation in which alone any peculiar tenet can maintain itself; the other to put that tenet into the melting-pot. Historically it undoubtedly played an important part in discrediting empirical allopathy. But laboratories of physiology and pharmacology are now doing that work far more effectively than homeopathy; and they are at the same time performing a constructive task for which homeopathy, as such, is unfitted. It will be clear, then, why, when outlining a system of schools for the training of physicians on scientific lines, no specific provision is made for homeopathy. For everything of proved value in homeopathy belongs of right to scientific medicine and is at this moment incorporate in it; nothing else has any footing at all, whether it be of allopathic or homeopathic lineage. "A new school of practitioners has arisen," says Dr. Osler, "which cares nothing for homeopathy and less for so-called allopathy. It seeks to study, rationally and scientifically, the action of drugs, old and new.

ECLECTIC COLLEGES

There are eight eclectic schools.[10] One of them—that in New York City—requires the regents' medical student certificate, i. e., a four-year high school education, for admission; the Cincinnati school must require an equal preliminary education of students expecting to practice in Ohio, others taking the matter into their own hands. Just how the instruction is thus accommodated to various levels is not clear. The remaining six schools have either nominal requirements or none at all.

None of the schools has anything remotely resembling the laboratory equipment which all claim in their catalogues. The Cincinnati institution possesses a new and attractive building, thus far meagerly fitted out; the New York school has a clean building with a chemical laboratory in which elementary chemistry can be and apparently is taught properly. It has little else; a small room for the microscopic subjects, but no adequate equipment for teaching them; a few thousand books, mostly old; a few models, a lantern, etc.—and this is the most satisfactorily equipped of all the eclectic institutions. . . .

[9] Jour. Am. Inst. Homeopathy, 1909, No. 11, i, 537; The Journal A. M. A., Aug. 14, 1909, pp. 556, 557, gives figures somewhat lower; 889 instead of 1009; 209 instead of 246. The discrepancy does not alter our interpretation.

[10] One each at Los Angeles, Kansas City (Kansas), St. Louis, Lincoln (Nebraska), Cincinnati, New York City, and two at Atlanta.

So far as sectarian creeds go, there is, of course, no reason why these schools should be elaborately equipped for scientific instruction. They talk of laboratories, not because they appreciate their place or significance, but because it pays them to defer thus far to the spirit of the times. Culpable indeed they are, however, for their utter failure to make good what their own tenets prescribe. The eclectics are drug mad; yet, with the exception of the Cincinnati and New York schools, none of them can do justice to its own creed. For they are not equipped to teach the drugs or the drug therapy which constitutes their sole reason for existence.[11]

OSTEOPATHIC COLLEGES

The eight osteopathic schools[12] fairly reek with commercialism. Their catalogues are a mass of hysterical exaggeration, alike of the earning and of the curative power of osteopathy. It is impossible to say on which score the "science" most confidently appeals to the crude boys or disappointed men and women whom it successfully exploits. "In no case has a competent osteopath made a failure in his attempt to build up a paying practice. . . . His remuneration, counted in dollars, will be greatly in excess of what he could reasonably expect in most other lines of professional work."[13] "It is only fair to say that many of our graduates are earning as much in single months as they were formerly able to earn by a full year's work."[14] "The average osteopath has a better practice than ninety out of every hundred medical practitioners."[15] "A lucrative practice is assured to every conscientious and capable practitioner."[16] "The graduate who does not make as much as the total cost of his osteopathic education in his first year of practice is the exception."[17] Standards these concerns have none; the catalogues touch that point very tenderly. At the parent school at Kirksville an applicant will be accepted "if he pass examinations in English, arithmetic, history and geography;" but if he should fail to meet these lofty scholastic requirements, he may be admitted anyway. In Massachusetts—the most homogeneously educated state in the Union—the Cambridge school diplomatically posts that "a diploma may be accepted or an examination be required if deemed advisable by the directors"—the word "is" being conspicuous by its absence; the Pacific College, "chancing it," finds that "most make good."

Whatever his notions on the subject of treatment, the osteopath needs to be trained to recognize disease and to differentiate one disease from another quite as carefully as any other medical practitioner. Our account of the sect proceeds wholly from this point of view. Whether they use drugs or do not use them, whether some use them while others do not, does not affect this fundamental question. Whatever they do, they must know the body, in health and disease, before they can possibly know whether there is an occasion for osteopathic intervention, and if so, at what point, to what extent, etc. All physicians, summoned to see the sick, are confronted with precisely the same crisis: a body out of order. No matter to what remedial procedure they incline—medical, surgical, or manipulative—they must first ascertain what is the trouble. There is only one way to do that. The osteopaths admit it, when they teach physiology, pathology, chemistry, microscopy. Let it be stated, therefore, with all possible emphasis that no one of the eight osteopathic schools is in position to give such training as osteopathy itself demands. The entire course is only three years. In so simple and fundamental matter as anatomy—assuredly the corner-stone of a "science" that relies wholly on local manipulation—they are fatally defective. At Kirksville the accommodations are entirely unequal to the teaching of its huge student body. Hence the first year is devoted to text-book study of anatomy, part of the second year to dissection; at Kansas City they consider that the student dissects better if he has learned anatomy first; hence dissection comes in the latter half of the course, being completed just one-half year before graduation. The supply of material is also scant; the school had had one cadaver early in the fall and was looking ahead to a second the latter part of the winter. The Los Angeles college has a small room with five tables for a student body numbering 250; it solves the difficulty by giving separate squads two hours a week each. At Philadelphia the department of anatomy occupies an outhouse, whence the noisome odor of decaying cadavers permeates the premises. Other subjects fare even worse. A small chemical laboratory is occasionally seen—at Philadelphia it happens to be in a dark cellar. At Kirksville a fair-sized room is devoted to pathology and bacteriology; the huge classes are divided into bands of 32, each of which gets a six weeks' course, following the directions of a rigid syllabus under a teacher who is himself a student. At Cambridge pathology comes in the last year. A professor in the Kansas City school said of his own institution that it had practically no laboratory at all; the Still College at Des Moines has, in place of laboratories, laboratory signs; the Littlejohn at Chicago, whose catalogue avers that the "physician should be imbued with a knowledge of the healing art in its widest fields, and here is the opportunity,"[18] has lately in rebuilding wrecked all its laboratories but that of chemistry without in the least interfering with its usual pedagogic routine.[19] . . .

The mercenary character of osteopathic instruction is nowhere more conspicuously displayed than in the dispensaries, designed in theory to turn a humanitarian impulse to educational account. The osteopathic schools insert a cash nexus: the patients almost always pay. At Kansas City students give treatment to patients who pay three dollars a month; those paying more are treated by the professors. At Kirksville two dollars a treatment is charged. The cases are mostly chronics, an instructor being present at the first treatment; afterward, only if summoned. At Los Angeles the cheapest obtainable treatment is three dollars for "examination" and one month's treatment before the class; at Des Moines the "professor administers to high-priced patients, the students to others."

The eight osteopathic schools now enroll over 1300 students, who pay some $200,000 annually in fees. The instruction furnished for this sum is inexpensive and worthless. Not a single full-time teacher is found in any of them. The fees find their way directly into the pockets of the school owners, or into school buildings and infirmaries that are equally their property. No effort is anywhere made to utilize prosperity as a means of defining an entrance standard or developing the "science."[20] Granting all that its champions claim, osteopathy is still in its incipiency. If sincere, its votaries would be engaged in critically building it up. They are doing nothing of the kind. Indeed, in none of the sectarian schools does one observe progressive effort even along the lines of its own creed. And very naturally: dogma is sufficient unto itself. It may not search its own assumptions; it does well to adopt from the outside, after forced restatement in its own terms.[21]

In dealing with the medical sectary, society can employ no special device. Certain profound characteristics in one way or another support the medical dissenter: now, the primitive belief in magic crops up in his credulous respect for an impotent drug; again, all other procedure having failed, what is there to lose by flinging one's self on the mercy of chance? Instincts so profound cannot be abolished by statute. But the limits within which they can play may be so regulated as to forbid alike their commercial and their crudely ignorant exploitation. The law may require that all practitioners of the healing art comply with a rigidly enforced pre-needs to be just as intelligent and mature as a student of scientific medicine; and he is no easier to teach; for during the first and second years, at least, he is supposed to be doing precisely the same things.

---

[11] The physiomedical sect can be dismissed in a note. It had three schools in 1907; only one, that in Chicago, is left. There were 149 physiomedical students in 1904; there are now 52; there were 20 graduates in that year, 15 in 1909.

[12] One school is found in each of the following cities: Chicago, Des Moines, Kirksville (Missouri), Kansas City (Missouri), Philadelphia, Cambridge (Massachusetts), and two at Los Angeles.

Case of Holoacardius Acephalus.—A case of holoacardius acephalus has been reported by Harry Jackson (*Tr. Chicago Path. Soc.*, April 1, 1910). The case occurred in the practice of Dr. A. E. Budde, Norway, Mich. The mother was 19 years of age and the pregnancy a second one of nine months' duration. The diagnosis had been pregnancy with tumor. A normal, viable, 3½ pound male child was delivered, followed by the supposed tumor, which showed a body and two legs, the head and arms being absent. The legs were of uneven length. There were no toes. Two cm. from the anterior extremity of the body was a hernial sac at the site of the umbilicus which contained cells of small intestine, and to the sac the cord was attached. Two cm. from the posterior extremity on the ventral surface was a small penis-like structure. There was no anal opening. The radiograph showed a fairly well-developed skeleton. There were eight ribs on each side of the vertebral column of 14 vertebra. The scapulæ were present but there were no clavicles or bones of the arms or skull. Having no heart, the specimen was dependent on the heart of a twin fetus for its circulation. The two fetuses had their origin in a single ovum as is evidenced by the single placenta and single chorion.

Book Notices

MODERN MEDICINE. Its Theory and Practice in Original Contributions by American and Foreign Authors. Edited by William Osler, M.D., Regius Professor of Medicine in Oxford University, assisted by Thomas McCrae, M.D., Associate Professor of Medicine and Clinical Therapeutics in the Johns Hopkins University, Baltimore. Vol. VII, Diseases of the Nervous System. Cloth. Price, $6 net. Pp. 969, with illustrations. Philadelphia: Lea & Febiger, 1910.

This is the last volume of this work. It has taken about three years to complete the publication, and in view of the magnitude of the undertaking, it hardly seems possible that the seven splendid volumes could have been issued in a shorter time. The authors of the present volume are: L. F. Barker ("Introduction to Diseases of the Nervous System"); E. Bramwell ("Sclerosis of the Brain and Diseases of the Meninges"); Charles W. Burr ("Neurasthenia; the Traumatic Neuroses and Psychoses"); E. F. Buzzard ("Diffuse and Focal Diseases of the Spinal Cord"); Joseph Collins ("Topical Diagnosis of Disease of the Brain, Aphasia"); Harvey Cushing ("Tumors of the Brain and Meninges: Hydrocephalus"); Gordon M. Holmes ("Diseases of the Peripheral Nerves"); Smith Ely Jelliffe ("Migraine, Neuralgia, Professional Spasms, Occupation Neuroses, Tetany"); D. J. McCarthy ("Paralysis Agitans, Chorea, Choreiform Affections, Infantile Convulsions"); Colin K. Russell ("Combined Diseases of the Spinal Cord"); B. Sachs ("Amaurotic Family Idiocy"); E. C. Southard ("Acute Encephalitis and Brain Abscess"); W. G. Spiller ("Diseases of Motor Tracts"); W. P. Spratling ("Epilepsy"); E. W. Taylor ("Diseases of the Cerebral Nerves"); H. M. Thomas ("Diseases of the Cerebral Blood-Vessels"). It would be out of the question to review critically the monographic articles of all these contributors; it must suffice to point out again, as has been done in the case of the preceding volumes, that each contributor is qualified by special study to write on the subject or subjects assigned to him. That the contributors in general are leading men is apparent to any one at all familiar with the present state of the general literature on diseases of the nervous system so far as this country, Canada and Great Britain are concerned. We note that the consideration of mental diseases has been omitted. There are 37 plates, many of them of great value, as well as a number—not very large—of figures in the text. The present volume in every way measures fully up to the high standards of the previous volumes. In addition to the volume index there is an index to the whole work; this general index covers more than 50 pages and seems to be a comprehensive one. There is no authors' index.

Viewed as a whole, "Modern Medicine" is a production of great merit and usefulness. The various parts are well balanced; the editors have been uniformly fortunate in the choice of contributors; the result is a reliable and comprehensive picture of the knowledge of general medicine of our times. The editors and publishers have rendered the English-speaking medical world a large service.

DIE FORENSISCHE BLUTUNTERSUCHUNG. Ein Leitfaden für Studierende, beamtete und sachverständige Aerzte und für Kriminalisten. Von Dr. Otto Leers, Assistent der königlichen Unterrichtanstalt für Staatsarzneikunde an der Universität Berlin. Paper. Price, 6 marks. Pp. 212, with illustrations. Berlin: Verlag von Julius Springer, 1910.

To compare the manner of conducting examinations in medicolegal cases by the officials of any fair-sized German city with the procedures employed under the prevailing system of coroners and coroners' physicians in this country, would be ridiculous. Only when political or financial prominence demands special investigation do we see anything resembling a scientific handling by experts, who are usually called in after police, coroners and undertakers have spoiled everything possible. Therefore we fear that Leers' concise monographs on medicolegal blood examinations will not have so large a clientele in America as in countries that have fewer cases to investigate and more officials competent to investigate them.

It is an excellent treatise on the subject, giving a full and clear statement of methods and their proper valuation, in surprisingly small space. All standard means of studying blood and blood-stains for legal purposes are described, including not only the chemical, physical and microscopic procedures, but also the technic of the biologic methods by means of the precipitin, complement-fixation and anaphylaxis reactions. About one-half the book is given to these biologic methods, and a good bibliography adds much to its usefulness. The author has evidently planned to supply the needs of students and physicians who are taking a course of instruction in medicolegal methods, and has succeeded admirably in this; at the same time the book will be useful to those wishing to learn the value assigned to the newer methods by an expert; it will also be a starting-point for special consideration of the application of existing methods in any case calling for detection or identification of blood or tissue proteins.

SURGERY, ITS PRINCIPLES AND PRACTICE. By Various Authors. Edited by William Williams Keen, M.D., LL.D., Emeritus Professor of the Principles of Surgery and of Clinical Surgery, Jefferson Medical College, Philadelphia, and John Chalmers DaCosta, M.D., Professor of the Principles of Surgery and of Clinical Surgery, Jefferson Medical College, Philadelphia. Volume V. Cloth. Pp. 1274, with illustrations. Price, $7 net. Philadelphia: W. B. Saunders Co., 1909.

In this, the fifth and last volume of this work, is found the most complete and comprehensive exposition of the subject of surgery of the vascular system (by Matas) that has appeared in any language. It is practically a monograph on the subject, comprising as it does the first 350 pages of the volume.

Surgery of the pericardium and heart, arteriorrhaphy, arteriovenous anastomosis, aneurismorrhaphy, together with all the recent experimental work done along these lines, are very thoroughly covered. The chapter is a model of completeness and one of the most valuable of the entire system. Following is a chapter on the "Surgery of the Female Genito-urinary Organs" which is a more complete exposition of the subject than is usually found in works of this kind. Among the newer subjects which are found discussed in this volume may be mentioned "Surgery of Accidents," "Surgery of the Parathyroid Bodies," "Intracranial Surgery of the Auditory Nerve," "Local and Subarachnoid Anesthesia," "Surgery of the Infectious Diseases" and "The Legal Relations of the Surgeon."

The authors, editors and publishers are to be congratulated on the excellence of their work and the whole profession for having been favored with such a master production.

EDUCATION IN SEXUAL PHYSIOLOGY AND HYGIENE. A Physician's Message. By Philip Zenner, Professor of Neurology in the Medical Department of the University of Cincinnati. Cloth. Price, $1 net. Pp. 126. Cincinnati: The Robert Clarke Co., 1910.

This book, intended more particularly for the public, is significant both as a message and a sign. As a message it brings to the people the mature thought of one of the ablest members of the medical profession on a subject of fundamental importance to society. It gives an account of an actual experiment, a demonstration of natural and beneficent sex culture in a public school. It teaches, furthermore, what ought to be taught in families as well as in schools, namely that sexual disease in the individual is the unit of social disease in the race. From this starting point the book treats of means that the medical profession has already recognized and that the public is beginning to recognize as the only logical method of solving the great problem that lies at the foundation of social welfare. As a sign of the times the book is especially significant. It reveals in its pages the fact that our schools for the masses are already taking up this question. It shows, furthermore, that the medical profession is giving careful study to these great sociologic problems and is issuing popular books of scientific value on questions that have too generally been left to ignorant and irresponsible writers. And, finally, it is a sign that the agitation conducted by the social purity associations and the eugenic organizations of the country is bearing worthy fruit. The style is lucid, while the subjects are plainly but delicately treated. It is a work that physicians can recommend when consulted, as they frequently are, about teaching the young on sex questions. It ought to be in the hands of every school teacher and parent.

LEHMANN'S MEDIZINISCHE ATLANTEN. Band vii. Atlas und Grundriss der Röntgendiagnostik in der inneren Medizin. Herausgegeben von Dr. med. Franz M. Groedel, Bad Nauheim. Cloth. Pp. 338, with 297 illustrations. Price, 24 marks. München: J. F. Lehmann's Verlag, 1909.

This work is not intended as a complete exposition of the subject for the use of the expert in Röntgen technic, nor does it take up the question of the use of the x-ray as a therapeutic agent, but is intended for the internist who uses the x-ray as an aid in the diagnosis of internal conditions. In the opening chapter is a brief description of the necessary apparatus, tubes, tables, screens, etc., with directions for their care and use. The various organs are then taken up and considered in detail, first the normal relations and then the pathologic conditions. Considerable attention is given to diseases of the heart and of the stomach and the value of orthodiagraphy in the diagnosis of the former and of the use of bismuth in the latter are well brought out. The changes which occur in the skeleton in connection with general diseases such as cretinism, myxedema, rachitis, Barlow's disease, osteomalacia, osteitis deformans, toxigenic osteoperiostitis, syphilis, tuberculosis, the arthritides, acromegaly, etc., are also presented. The work is extensively illustrated with 114 cuts in the text and an atlas of 173 autotypes and 122 photographs. A bibliography of thirty odd pages completes the work.

STUDIEN UEBER DIE BEI PERITONÄALEN INFEKTIONEN APPENDIKULÄREN URSPRUNGS VORKOMMENDEN SAUERSTOFFTOLERANTEN SOWIE OBLIGAT ANAËROBEN BAKTERIENFORMEN mit besonderer [illegible] ihrer Bedeutung für die Pathogenese derartiger [illegible] Runebc [illegible] n der Chir- [illegible] zu [illegible] Pp. 303, with illustrations. Berlin: Verlag von S. Karger.

This is a careful study of the subject of peritonitis of appendiceal origin. The author shows that the peritonitis in these cases is seldom due to a single form of organism and that the mere fact that but one variety of organism grew on the culture medium is no indication that the peritonitis was due to a simple infection. In most of the cases he finds a multiple infection and shows that the reason why they have usually not been found is that they are anaerobic in their nature and thus do not grow under the ordinary cultural methods. Even in those cases seen early with a slightly turbid serous exudate which ordinarily have shown no bacterial growth, and which therefore have been termed toxic or chemical peritonitis, he finds anaerobic bacteria of various kinds if suitable cultural methods are employed. Naturally the organisms found are those present in the intestine but they do not all live nor are they found in the same relative numerical proportion in the peritoneal exudate as in the intestine. The work contains much valuable information.

WHAT YOU OUGHT TO KNOW ABOUT YOUR BABY. By Leonard K. Hirshberg, M.D. A Text-Book f[illegible] on the Care and Feeding of Babies, with Questions and [illegible] Prepared by the Editor. Cloth. Price, 25 cents. Pp. [illegible] New York: The Butterick Publishing Co., 1910.

The *raison d'être* of this book, as sufficiently expressed in the preface, is that "more and more the doctor is interpreting it as his mission to teach people how to keep well. And the place to begin is with the babies." In a graphic and forceful way Dr. Hirshberg explodes old theories, superstitions and customs in regard to the rearing of babies, and points out the sensible, the modern way of carrying out this responsible duty and the inculcation of correct habits up to the period of adolescence. The causes of the common but dangerous diseases of childhood and the way to avoid them are explained in a practical way, and the responsibility of parents, through misguided affection and coddling, lack of knowledge or carelessness, for their occurrence is emphasized. The questions and answers at the end of each chapter bring to the consciousness of the reader in a pointed, concrete way the things to be avoided and the things to be observed. It is a practical book and will help in the education of the public in health matters.

THE CONQUEST OF DISEASE THROUGH ANIMAL EXPERIMENTATION. By James P. Warbasse, M.D., Surgeon to the German Hospital, Brooklyn. Cloth. Price, $1 net. Pp. 175. New York: D. Appleton & Co., 1910.

This little book is a timely publication and is commended to those who wish a logical, conservative and rational presentation of the case for animal experimentation. The book is based on addresses given before the New York Academy of Medicine, the Medical Society of the County of Kings, and the Brooklyn Institute of Arts and Sciences; it contains papers on "The Study of Living Animals," "What is Meant by Animal Experimentation," "The Technic of Animal Experiments," "The Meaning of Pain" and "The Relation of Animal Experimentation to Physiology, Surgery, the Practice of Medicine, Hygiene and Diseases of the Lower Animals." The book is recommended to county societies for distribution to the public, and for public libraries. It is especially suitable for school libraries. Dr. Warbasse deserves the thanks of medical research workers for the preparation of this volume.

HANDBUCH DER SERUMTHERAPIE UND EXPERIMENTELLEN THERAPIE. Ein Handbuch fur Klinik und Praxis. Herausgegeben von O. Wolff-Eisner, Berlin. Paper. Price, 12 marks. Pp. 408, with illustrations. Munich: J. F. Lehmanns Verlag, 1910.

This book consists of short and concise articles by a number of the more prominent active workers in the field of immunology and experimental therapy. The object is to provide the clinician with an authoritative source for ready reference in regard to serotherapy, vaccine therapy, organotherapy, etc., in their immediate practical bearings. The various chapters are written by men who have made the subjects discussed the object of personal study and investigation. The theoretical discussion is limited to the explanation of the underlying principles of the various methods. There is no question but that the practitioner will find this a useful book; it will help him to a better understanding and utilization of the results of progress in biologic science so far as they concern therapeutics.

ATLAS DER ANATOMIE DES MEDIASTINUM IM [illegible] Von Dr. Friedrich Albin Hoffman, o. ö. Professo[illegible] *medizinischen Poliklinik an der Universität Lei*[illegible] five radiographic plates. Price, 12 marks. Leipsic: Dr. Werner Klinkhardt, 1909.

This atlas consists of 25 plates, nearly life size, of Röntgenographs of the chest taken at definite angles through the body so as to present to view, as it were, the contents of the thorax from every possible direction.

The author correctly believes that the normal anatomy should be studied from the viewpoint of the x-ray plate before the attempt is made to study the pathologic picture and the object of these plates is to furnish some reliable data covering this particular portion of the body. The plates are very good, although they have lost somewhat in clearness of detail by repeated printing, a loss which is partially compensated for by the descriptive diagrams and explanatory text accompanying each plate.

HYGIENE OF PREGNANCY. By E. H. Harris, M.D., Higginsville, Mo. Paper. Price, 10 cents. Pp. 23.

This little pamphlet, intended for prospective mothers, after giving practical advice and instruction in regard to the diet, the value of fresh air, care of the skin, bowels, the breasts, the clothing to be worn and the correct attitude of mind to be cultivated during pregnancy, then takes up the subject of the approaching labor and the preparation for it and for the newly-born baby, its outfit and its hygienic care, the bath, feeding, sleep, dressing, necessity of open air, observation of the weight, the desirability of a quiet environment for the young child, weaning, etc., and closes with some sensible hints in regard to the rearing of the baby during its first year.

Pulmonary Tuberculosis and Its Complications. With Special Reference to Diagnosis and Treatment for General Practitioners and Students. By Sherman G. Bonney, M.D., Professor of Medicine, Denver and Gross College of Medicine, Medical Department of the University of Denver. Second Edition. Cloth. Price, $7 net. Pp. 955, with 243 illustrations. Philadelphia: W. B. Saunders Co., 1910.

In our review of the first edition of Bonney's work, we expressed the opinion that it was one of the best works on the subject of tuberculosis. The second edition contains a careful conservative review of newer developments and five new chapters are added. It is the work of an experienced clinician, which makes it particularly valuable to the practitioner, and being the work of one author, it possesses a unity which is often lacking in systems.

Consumption: Its Prevention and Home Treatment. A Guide for the Use of Patients. By H. Hyslop Thomson, M.D., Medical Superintendent Liverpool Sanatorium. Cloth. Price, $1. Pp. 75, with illustrations. New York: Oxford University Press, 1910.

This little book is written to be a guide for the use of patients. The author is medical superintendent of the Liverpool Sanatorium and a series of lectures delivered to patients in this institution form the basis of this volume. It contains a clear, simple statement of what tuberculosis is, how it is transmitted, and how patients must live to get well. Its simplicity, directness and good sense ought to make it a useful guide for curable consumptives. It is not intended to take the place of the physician but to supplement his directions.

Society Proceedings

OHIO STATE MEDICAL ASSOCIATION

Sixty-fifth Annual Meeting, held at Toledo, May 11-13, 1910

(Continued from page 1897, Vol. LIV)

President's Address: The Relation of the Medical Profession to the Public

Dr. W. H. Snyder, Toledo: It is manifestly impossible for so complex and necessary a science as medicine to live without a certain amount of easy articulation with the public. If the profession had not lived so much within itself, but, rather, had spread its ideals and discoveries before the public, antivivisection, Christian science, osteopathy, optometry and mental healing could not have gained ground, except with those who are mentally incompetent. Well-known weekly and monthly magazines have during the past two years probably done more to educate people along correct lines of medical thought than any other single agency. They reach a larger number of people, who are largely visualists, and must see in cold print what is intended for them to know, and, too, are regarded as stating the case more impartially than physicians would. I prophesy that the time will come when the medical profession will be compelled to print a magazine for lay circulation along these very lines, and I suggest that the association seriously consider the establishment of a bureau at Columbus, which would constantly be influencing the public thought through the newspapers, magazines and public addresses.

One of the lamentable things in Ohio is the condition of the state institutions, especially those for the insane; the most that can be said for them is that they are houses of detention and not hospitals. The medical profession of the state should take it on itself to submit a list of medical men available as superintendents for this work, and recommend to the legislature that some action be taken which will lead to an adoption of executive and medical supervision. Too much attention is paid to the per capita cost per year, rather than to the results from a medical standpoint.

The association should adopt the plan of the parent organization of having a president-elect, and an earnest inquiry should be made into the virtues of the plan for medicolegal defense, such as had been adopted by the Toledo Academy of Medicine.

The Principles of Medical Defense as Applied to the Ohio State Medical Association

Dr. Willard J. Stone, Toledo: Since most so-called malpractice suits against physicians arise from misunderstanding or for purposes of extortion, a stiff defense by a firm of attorneys experienced in such work is usually enough to lessen the ardor of any adventurer or unscrupulous lawyer. Physicians who are members of such an organization are more careful in opinions expressed regarding the work of their associates. The defense deals only with civil action brought against members of the society; no attempt is made to excuse negligence or culpability. In such case physicians are advised to settle the matter in hand as seems best to the executive committee and the attorneys. In all states which have so far tried the plan, it has proved successful from a financial point of view. It furnishes members a cheap insurance, but not for profit, and such a feature greatly increases membership in the state organization. The number of malpractice suits has been decreased at least 25 per cent. in states which have adopted the medical defense feature.

LEGISLATIVE NOTES

Condemnation of Benzoate, Etc.

A motion was carried deprecating the use of benzoate of soda and similar chemical preservatives in the preparation of foodstuffs intended for human consumption, and urging on Congress such modification of the Food and Drugs Act as will make their use impossible.

A telegram was sent to the governor of the state urging him to use his power of veto against the optometry bill.

Eugenics and the Sterilization of Criminals

The committee on vasectomy reported that a bill providing for the sterilization of habitual criminals had been prepared, but was buried in committee. The laity is little less informed on the need of such legislation than is the medical profession itself. The idea of human sterilization is repugnant to the average man, and unless he studies the subject carefully and also learns what has been done, he will turn from any such proposal in disdain. He has little patience even with the reasonable proposal to emasculate the habitual sexual criminal. It is the opinion of this committee that the subject of parenthood and race culture, the so-called science of eugenics, should receive vastly more attention than is accorded to it in the reading and study of the average physician, to say nothing of the average layman. It can be laid down as an axiom that there can be no interference with child life after the union of the cells concerned in reproduction; all that then can be done is to provide for the child's environment and education. The only means we have to redress the imbalance which threatens to engulf us in the relative rates of reproduction in the inferior and superior classes is to prevent in some way the multiplication of the former and to encourage it in the latter. Nature preserves the balance by killing the unfit in all living species except man. Savage races are subject to the same law. We who are moral and humane and have not in our own hands the issues of life and death, must preserve and elevate the race by preventing the unfit from ever coming into existence at all. We must replace Nature's relative death rate by an intelligent relative birth rate. This means vast economy in life, in money, in time, in suffering. It is merciful and supremely moral. It is natural at bottom, but it is Nature raised to its highest power in the moral intelligence of man. In view of these truths the committee recommended that the state committee on public policy and legislation be charged with the duty of continuing the agitation in published articles in our journals and through other channels for the education of the profession and the people, and that a bill embodying the principle of sterilization of habitual criminals be introduced for enactment at the next session of the Ohio legislature.

National Department of Health

A resolution was passed endorsing the bill introduced in the Senate by Senator Owen to establish a national department of public health.

A Section on Sanitary Science and Hygiene was organized.

Trend of Laboratory Diagnosis in the Past Ten Years

Dr. Francis Carter Wood, New York: The time has come when it is absolutely necessary for the practitioner of medicine and the laboratory specialist to unite in their work, if the patient is to receive the best treatment, and medicine is to be advanced along practical lines. In the past, many laboratory investigations have been of little value, because they lack direct application to live conditions and are much too theoretical. The practitioner who had no laboratory training was hampered in the diagnosis and treatment of his cases. The tendency is, even now, noticeable, in medicine, to place the treatment of a few infectious diseases in the hands of men whose training has chiefly been of a laboratory nature, examples of which may be cited, the application of tuberculin and the vaccine therapy. Laboratory methods consist of those which the practitioner himself should regularly employ, and those which, on account of their very complication, must be carried out in a fully equipped laboratory and only by specially trained men. However, the physician must have full knowledge of the relative value of the laboratory and clinical symptoms. In some diseases the laboratory findings are of the utmost importance; in others of relatively small value. The subcutaneous injections of tuberculin, the Von Pirquet, Moro and Detre tests, require a somewhat extensive experience to use and interpret them intelligently. This is also true of the therapeutic use of tuberculin. The vaccine treatment of Wright should be confined to men who have had special laboratory training and experience. Many of the unsuccessful cases recorded and some of the unfortunate results that have been obtained by the use of the vaccine therapy are undoubtedly due to the injudicious employment of this method in unsuitable cases.

Another important method in diagnosis and treatment, which must be carried out by laboratory men, is the Wassermann reaction. This test I consider as possibly the most important laboratory contribution to diagnosis of the past ten years. It is of great importance in the inspection of wet nurses, in quieting those who suspect, without reason, that they may have contracted syphilis, and life insurance companies might with advantage use the test in doubtful cases. Certainly those who give a positive reaction could not be considered ordinary risks.

But laboratory and instrumental methods by no means replace the clinical history and careful examination of the patient. In probably 90 per cent. of persons treated in general practice the use of laboratory methods adds but little to diagnosis or treatment, but in the remaining 10 per cent. such tests might be of vital importance. Especially is this true of persons to be treated by the newer sera or bacterial products, where an absolutely accurate diagnosis is necessary. The main fact to be kept in mind is that the time has come when there can be no separation of the clinical and laboratory aspects of medicine, and patients have a right to demand every means which will give them the best hope of cure.

Trivialities and Progress

Dr. John F. Binnie, Kansas City, Mo.: A consideration of some apparently self-evident principles, observations and investigations and of the benefits accruing from their recognition is not only interesting but will encourage one to pay more attention to common sense in an age when we are liable to be swamped by the flood of wierd technical terms and weirder processes constantly flowing from the laboratories. While exact laboratory and experimental work is an absolute essential in progress, unfortunately too common though unavoidable divorce of the laboratory from the clinical study is liable to render the laboratory observer tyrannical or bigoted.

From the earliest days the milkmaid knew that her milk would sour unless her pans were thoroughly cleansed and scalded; the housewife knew the preserves were safe if, after being thoroughly boiled, they were kept free from air pollution; the plainsman knew that his jerked meat if well dried was an assured asset. And yet surgeons were blind to the significance of these observations until the researches of Pasteur were published in France and applied to practical surgery by Lister in Glasgow. In early operation for rupture opposing edges were brought together and sutured; now all successful operations for inguinal hernia aim at the restoration of the canal by securing apposition of surfaces instead of edges. The whole principle of the closure of hernial openings is based on the fact that it is much easier to gum two sheets of paper together by their faces than by their edges. Such principles are so absurdly simple that it seems almost an impertinence to mention them, and yet surgeons were blind to them. The marvelous advance of bacteriology has been rendered possible by the simple discovery of the separation of the bacteria in a solid culture medium.

Some Germans recently discovered that a ganglion is the result of a colloidal degeneration of connective tissue, and that bursæ seem to have a similar origin. Comparison of the histology of ganglia, bursæ and joints show the three structures very similar if not practically identical. Nélaton and others were struck by the fact that non-union of fractured bones was commonly due to interposition of muscle, etc., between the fragments, hence in cases of ankylosis of the lower jaw they excised the temporo-maxillary joint and filled the osseous defect with a flap of tissue from the temporal muscle. John B. Murphy put these things together with the spark of genius. Why would not similar degeneration take place in flaps of tissue made to envelop opposed sawn surfaces of bone? The result is a new chapter added to surgery, viz.: arthroplasty. Sprains are no longer treated by complete rest, but by means of adhesive strips strain is taken off the injured structures and the patient thus protected and urged to use the injured joint, with the result that the active movement of the parts encourages absorption of the exudates and encourages nutrition while discouraging the formation of crippling adhesions and callosities. In vascular surgery the observation of the mesentery of the frog showed that where the blood stream slows the corpuscles congregate and the circulation stops, because the mesentery so quickly dries, but if kept moist in salt solution it can be observed uninterrupted; the fact that an eye kept open and dry will develop conjunctivitis; that where a loop of intestine is pulled out it quickly loses its normal luster, becomes dry and later covered with lymph, so that it readily adheres to almost anything with which it comes in contact—all these things our predecessors were blind to. Physicians will protect exposed abdominal contents with dry gauze, than which there could be no material better adapted to dry the delicate peritoneum and produce the phenomena of inflammation. If the gauze be wrung out of warm salt solution, or, better, out of warm liquid petrolatum, then it becomes a real protection not only against infection but against evaporation. That the Criles and the Carrels have succeeded in arteriorrhaphy where their predecessors failed lies in the fact that the successful experimenters prevented evaporation and drying of the intima, recognizing the fact that blood will coagulate on the intima of a vessel when that intima is inflamed, and that any delicate serous or mucous membrane exposed to the air becomes dry by evaporation and so inflamed. The rest of us had looked at the blood circulating in the frog's mesentery and had known of the necessity of keeping the mesentery moist lest the circulation stop; but we were not seers—we could not see the obvious and so failed in progress.

Ulceration of the Larynx Following Intubation in Membranous Croup

Dr. J. M. Phillips, Columbus: Out of four hundred and twenty cases I have observed this sequel twelve times. The exciting cause is undoubtedly the pressure which the tube exerts on tissues already lowered in vitality as a result of diphtheritic inflammation, and while the metal and hard rubber tubes seem equally apt to produce ulcers, undoubtedly a tube which is too large or which is awkwardly or forcibly introduced is more likely to produce ulceration than one which fits exactly and is introduced by a skilled hand. The early symptoms are not easy to recognize. In one class of cases when the tube is removed the child is unable to obtain a single inspiration, or else shows rapidly increasing dyspnea, making a reintubation necessary in a few hours, in which cases the ulcers have probably already formed and the larynx is swollen and softened. In a second class the patient does nicely for several days, then gradually develops the symptoms of laryngeal obstruction, and operative interference becomes imperative. At first I believed the dyspnea was due to a reflex spasm of the vocal cords, but, having an opportunity to examine with the laryngoscope, I saw the cords open, but the larynx was partially occluded by a collapse of its anterior wall. The softening of the cricoid and thyroid cartilages, which have to bear the greater part of atmospheric pressure during inspiration, permits them to collapse during inspiration as a result of this external pressure. In all cases after ulceration is well advanced the most pronounced symptom, and one almost pathognomonic of ulceration, is the repeated coughing up of the tube, the expulsion of which is followed immediately by intense dyspnea or even asphyxia. In hospital practice most of these patients die from bronchopneumonia, due to aspiration into the deeper bronchi of pus from the ulcerating surfaces. In private practice most of the patients cough up the tube and die from asphyxia before the physician can reach them. The treatment is unsatisfactory. Six patients with suspected ulceration recovered when treated by sedatives and by removing the tube quickly or allowing it to be coughed up. Under expectant treatment there were six deaths from bronchopneumonia and one from asphyxia, and one recovery with partial stenosis of the larynx. After tracheotomies there was one death from asphyxia, two recoveries and one child which died of measles after wearing the cannula five months.

DISCUSSION

Dr. Thomas Hubbard, Toledo: In these days of antitoxin intubation is practically a lost art. The tendency now is to wait longer than one would in the pre-antitoxin days; consequently it is the most desperate class of cases that have intubation. These cases of deep ulceration and complications following intubation have been due to mixed infection rather than pure diphtheritic infection. Shurley of Detroit, in 400 cases, was able to study 30 for five years after intubation, and in only a few was there even the symptom of hoarseness. In other words, the slight erosions from the calcareous deposits on the tube rarely result in permanent injury. The size of the tube is important, not as regards the child's age, but the actual condition encountered, a smaller tube sometimes being required on account of the extreme swelling. Also the matter of introduction and extraction is most important. The old tubes, after the original methods of O'Dwyer, were the most perfect and satisfactory.

Pleurisy, Both as a Complication and as a Sequel of Lobar Pneumonia; Diagnosis and Treatment

Dr. James M. Anders, Philadelphia: While it is universally conceded that pleurisy is the commonest complication of the pneumonic process, it should be regarded as a complication only when the dry plastic variety is of marked severity, or pleurisy is accompanied by sufficient effusion to be easily demonstrable by means of the physical signs. There are instances of pleurisy of the plastic variety that clearly precede the development of a pneumococcal infection of the lung, and this class of cases has not received the measure of consideration that it would seem to merit. It is often difficult to distinguish such cases from those presenting identical signs, without the tendency to merge into pneumonic features; but an examination of the blood usually reveals a leukocytosis. The systemic prostration is greater and the temperature range higher than in non-pneumococcic pleurisies. It is well in suspects to attempt to demonstrate the pneumococcus in blood cultures. With regard to pleural effusions in children, as related to lobar pneumonia, two points deserve special notice: first, as compared with adults, purulent effusions from all causes are more frequent relatively than serous; and second, during early childhood not less than 75 per cent. of empyemata are due to the pneumococcus, according to the figures of Netter, Blaker and others.

The question of its bacteriologic cause is important. The pneumococcus is often found in a state of purity, but it may also occur mixed with the streptococcus, the staphylococcus, the tubercle bacillus, and rarely with other organisms. These facts have a practical bearing on the diagnosis, prognosis and treatment. Exploration with a needle in highly suspicious cases may be demanded, but shock, even of the slightest degree of intensity, is badly borne by pneumonia patients, and a small needle is to be preferred. A gradual fall of temperature in pneumonia rather than crisis, is often due to associated pleuritis.

The general features of pneumococcus empyema are usually more or less indefinite. If a complication, the temperature usually falls by lysis and an irregular fever curve may exist for weeks in unrecognized cases. Empyema as a sequel is usually easy to detect; irregular fever returns, the prostration increases, and there is rise of the leucocyte count. Spontaneous rupture should not be awaited. Exploratory operations will not only clear the diagnosis, but also accomplish the cure in a majority of cases. It is of the utmost importance to avoid the use of drugs that act as depressants in all pneumonia cases. Counter irritation in milder cases, and the complete putting to rest of the inflamed structures are advisable. The treatment of empyema is surgical. Somewhat massive doses of the tincture of the chlorid of iron is apparently efficacious.

AMERICAN NEUROLOGICAL ASSOCIATION

Thirty-sixth Annual Meeting, held in Washington, D. C., May 2-4, 1910

(Continued from page 1895, Vol. LIV)

Case of Resection of Dorsal Spinal Nerve Roots for Gastric Crises of Tabes

Drs. J. J. Thomas and E. H. Nichols, Boston: Aside from the case reported by Förster and Küttner, one other case has been found in the literature, reported by Bruns and Sauerbach, both operations having been done in the summer of 1909 and both followed by complete relief. Our patient was a man, 32 years old, a widower, with one healthy child, a girl of 13. The birth of this child was followed by three or four miscarriages of unknown cause. Syphilis was denied. The gastric crises began about eight years before, and in October, 1905, the abdomen was opened, but nothing abnormal was found, except a few adhesions of the omentum to the gall-bladder, which did not pull on the stomach. These adhesions were freed. The attacks continued and the man entered the hospital, Aug. 3, 1908; at that time his attacks came at intervals of one week to one month, and lasted from one to ten days with severe pain and vomiting, accompanied usually by diarrhea. There had been no loss of control of the bladder, but some diminution of sexual desire. No lancinating pains, no diplopia and no ataxia in walking or standing, but very slight ataxia in movements of legs with eyes closed. Hypertonicity in legs well marked. Pupils moderate size, regular and equal, reacting with accommodation, but not to light. Patellar and Achilles reflexes equal and present. At this time he had become habituated to the use of morphin and was taking about a grain a day. The attacks continued, gradually becoming more frequent, seldom a week passing without one. In August, 1909, the Noguchi serum test for syphilis was positive.

At the time of operation the weight, formerly 145 lbs., had fallen to 100 lbs., sensation for touch and pain was diminished on the chest from the third to fifth rib and the abdominal reflexes were lively. The left Achilles jerk had disappeared though the right one and the patellar reflexes were present. March 3, 1900, the 7th, 8th and 10th thoracic dorsal roots were cut. After the operation for a time there was severe twitching of the abdominal muscles at times and pain about the chest, which gradually diminished. He vomited once while still in the hospital after being given mercury by mouth and once after his discharge after eating beans, but neither time was there any pain, nor was the vomiting persistent, being over within an hour. There was the same condition on examination, but an absolute loss of the sense of touch and pain from the level of the sixth rib to three fingers breadth above the umbilicus and from this area no abdominal reflexes could be obtained, but it was present and increased on irritating the skin of the lower abdomen. The man regarded himself as cured of his crises, but had not gained in weight and was attempting to diminish his morphin and had reduced it to ½ of a grain a day.

DISCUSSION

Dr. J. K. Mitchell, Philadelphia: How does Dr. Thomas justify the diagnosis of locomotor ataxia with knee jerks still present? In the last year I have seen one case of tabes in which gastroenterostomy was done and two cases in which operation was done for gastric crises and two in which gallstones were hunted for. Presumably in none of these cases did the surgeons take the pains to examine either the knee jerks or the eye reflexes.

Dr. P. C. Knapp, Boston: I must confess that theoretically I am somewhat skeptical about the results of operating on the posterior roots for the gastric crises of tabes, because of the physiologic fact that the nerve supply of the stomach is dependent very much more on the vagus than on the sympathetic. Dr. Thomas' success, however, led me to have another patient, whose case is very similar to his, operated on by Dr. Blake a day or two ago. In answer to the objection Dr. Mitchell raised to the diagnosis in Dr. Thomas' patient, I would say that in the last few years, as well as previously, I have seen many cases with pretty clear tabetic symptoms but with retained ankle jerk.

Dr. H. Cushing, Baltimore: I would like to make an arrangement with Dr. Mitchell whereby I could turn over for his collection a list of cases of the kind he mentions of which I have cognizance in return for a list of cases of brain tumor long treated for gastric headaches. Just a day or two ago a patient, a woman who had very persistent crises with great pain, was transferred from the medical to the surgical side for operation, but when I saw her I decided to delay operation, as she was absolutely free from pain. I do not think any surgical cases of disease reported after they have been done a month really convey a fair general impression as to what the author's results are.

Dr. J. Collins, New York: I am very much in favor of the operation in cases that are intractable. In reference to knee jerks being present in tabes. I would say that in 10 out of 20 cases of tabes the knee and ankle jerks are present.

Dr. F. X. Dercum, Philadelphia: A man seen by me many years ago, long before we had resorted to the examination of the cerebrospinal fluid and the Wassermann test, had frightful suffering, apparently crises of tabes, though the knee jerks were retained. There was no marked disturbance of sensation anywhere, but there were markedly contracted pupils. The patient was a user of morphin, but on being persuaded to do without hypodermics 48 hours he had a good pupil, which responded to light. In other respects the symptoms varied somewhat. There were symptoms of a gastric nature. Dr. Keen excised a small gastric ulcer and the man recovered. I believe that this operation promises something in an otherwise very serious affection.

Dr. J. J. Thomas: I agree with Dr. Collins that we frequently make the diagnosis of tabes in the presence of knee jerks and ankle jerks. The reflex of the pupils was absent to light, although retained at first, and the man had marked hypertonicity, which I thought was fully as important to tabes as ataxia, and I felt justified in calling the case one of tabes. I made the Noguchi test and it was positive for syphilis. The count of the cerebrospinal fluid was not made. At operation there was found a marked degeneration of the pia.

Oculomotor Palsies Due to Vascular Constriction in Cases of Brain Tumor

Dr. Harvey Cushing, Baltimore: Oculomotor and particularly abducens palsies, more or less fluctuating in degree, often occur in cases of tumor and are included among false localizing signs. Various explanations have been offered for their occurrence. Contrary to the usual anatomic description, these nerves underlie the lateral branches of the basilar artery, which have a rubber band effect and so constrict the nerves as to block their transmission of impulses. The condition is most apt to accompany tumors of the posterior fossa.

A New Type of Pressure Myelitis

Dr. Graeme M. Hammond, New York: Author's observation is based on the study of seven cases. The pathologic conditions of this disease seem to consist of the development of an enormous amount of new bone tissue, which is spread over a number of vertebræ and adjacent rib ends, obliterating all articulations and giving the affected vertebræ and ribs the appearance of being one single piece of bone. The development of new bone also occurs within the vertebral canal and gives rise to compression of the cord, causing both sensory and motor symptoms, but eventually leading to the most intense rigidity of the entire voluntary muscular system below the level of the lesion. There was gradual development of the "bible back" or forward curvature of the vertebral column seen in spondylose rhizomelique, but in none of the cases was there any evidence of rheumatism.

DISCUSSION

Dr. B. Sachs, New York: I have seen a number of cases that have offered some difficulty in diagnosis, particularly in trying to make the differential diagnosis between such conditions as described and a simple myelitis. Within the last few months I have had two cases of absolute spinal rigidity. An *x*-ray picture was taken in one case and showed a condition very much like the one presented by Dr. Hammond. In this patient, a man of about 35, the rigidity of the spinal column was absolute from the third or fourth cervical vertebra to the very end of the spine. In fact, there was no movement possible of the body, except slight movement of the head forward and a slight lateral movement of both sides. There were extreme contractures and atrophies. The man as he now lies in bed has his knees so completely contracted that you can hardly put a hand between the posterior surface of the thigh and the posterior surface of the calf, the legs are locked together and there is absolutely no motion of any part of the leg, except of the toes. The atrophy is more extreme than I have ever seen it in any case of ordinary spinal origin. There is hardly a bit of tissue left; the skin seems as the bone. So far as the diagnosis is concerned I am not ready to suppose this represents an entirely new type of disease. I think these cases are closely related to the spondylose rhizomelique type. I hope that in all these cases of mysterious spinal disease an *x*-ray picture will be taken, for nothing is more serviceable in case of mysterious spinal disease in reaching a diagnosis when medical signs are wanting.

Dr. D. J. McCarthy, Philadelphia: My feeling is that we are dealing in these chronic cases of rigidity of the spine with not only a factor involving the bone and cartilages, but an involvment of the spinal dura on its external surface, and this should be examined very carefully microscopically. It is more rational to suppose that where you have an extensive process it would more likely be due to inflammatory changes in the dura, a condition localized to one group of joints. The bone changes are secondary and are not the primary disease.

Dr. W. G. Spiller, Philadelphia: I have not quite understood from Dr. Hammond the distinction between the type he has described and that which von Bechterew describes. Von Bechterew makes a distinction between his forms and those of Marie. There are in this connection two other kinds of disease. They are not likely to cause confusion in diagnosis, but they are interesting to mention. Eight or ten years ago Dr. Mills and I reported a case of a man who was paralyzed and had rigidity of the spinal column. We found that the dura was firmly adherent to the bodies of the vertebræ throughout the whole course of the spinal canal, and in removing the cord it had to be cut away inch by inch. I recently had an interesting case in a man who developed paralysis and exaggerated reflexes of his lower limbs. The disease gradually progressed upward, involving his left arm and then the other arm, and the course of the disease was only a few weeks. I found a growth on the outside of the dura which under the microscope shows probable endothelioma. This is the first case I have seen of real endothelioma developing primarily between the dura and the bodies of the vertebræ.

DR. G. M. HAMMOND: In regard to the case Dr. Sachs spoke of, I think there is no doubt that it is a case of spondylose rhizomelique; he has the muscle changes which go with such conditions. In none of my cases was there any ankylosis of the hip joints, or atrophy. The rigidity was a muscular spasticity just as we see in a myelitis of the crossed pyramidal tract with the attendant symptoms of clonus, Babinski reflex and exaggerated reflexes. This persisted until rigidity had become great. All these patients die. Not so with the cases of spondylose rhizomelique; many of the patients live on for years. I agree with Dr. McCarthy that the bone changes are secondary. In all the cases the first symptom elicited was the curvature and rigidity of the spine coming on three or four years before the first spinal symptom was apparent. In regard to the changes of the dura spoken of by Dr. Spiller, in the only case I have had a chance to examine the dura it showed no adhesion. So I doubt whether adhesions of the dura have anything to do with the symptomatology of this condition. It simply seemed to me that on account of the increase in the body tissue the spinal cord is gradually compressed and destroyed, and these patients die. I do not think it tallies at all with any of the cases described by von Bechterew. It may not be a new disease, but it is new to me and I have no doubt that when attention is called to it we will find a good many cases of similar type, but it is not that of spondylose rhizomelique.

Cyst (Possibly Traumatic) of Spinal Meninges Removed by Operation, with Recovery of Patient. Location of Centers for Testicular Sensibility

DR. CHARLES S. POTTS, Philadelphia: A farmer, aged 42, received a blow on the back eighteen years before coming under observation. No serious symptoms were caused at that time. Two years before admission to the hospital (12-8-09) he began to have attacks of severe shooting pains in the left hypochondrium. During the attacks the lumbar muscles of the left side were thrown into spasm. At this time a girdle pain extending through the umbilicus was also present. A few months before admission first noticed difficulty in walking. Examination showed a very ataxic gait. Muscular power of the legs good. K.J. plus, A.J. plus. Babinski on the right side. The cremaster reflex was present on the left side but absent on the right. Abdominal reflex absent. Station poor, heel-to-knee test poorly performed, unable to recognize the direction of passive movements of the toes. An area of possible hyperesthesia and hypalgesia extending about four inches below the right groin. Both testicles completely insensitive. Sphincters normal. The laminæ of the sixth, seventh, eighth, ninth and tenth thoracic vertebræ were removed. A soft growth, pronounced by the pathologist to be a *traumatic* cyst, was found extending subdurally from the lower angle of the wound (first lumbar segment) upward for about three inches. Complete disappearance of pain. Testicular sensibility returned and there was nearly complete disappearance of all the other symptoms.

Tumors and Cysts of the Spinal Cord and Its Envelopes

DR. CHARLES K. MILLS, Philadelphia: I will present the histories of three cases of intraspinal disease. The first was one of tumor of the lower cervical region; the second was a cyst of the thoracic region similar to those which have been described under the designation of circumscribed serous meningitis; the third was a sarcoma involving the cauda equina and lumbosacral roots, and to some extent the cord. The chief points of interest in the case of subdural cervical endothelioma were the exact localizing phenomena present—early pain at the upper pole of the growth as indicated by its distribution, the moderate but distinct atrophy and loss of power in the hands and fingers. Compression of the pyramidal tracts as shown by paresis and exaggerated reflexes in the lower extremity and impairment of the reflexes in the upper extremity on the side of the tumor. Anesthesia in the case was very slight and chiefly confined to tactile loss in the postaxial portion of the hand and forearm. After the operation contraction of the pupil and ptosis or pseudo-ptosis were present, these apparently being caused by injury or section of communicating branches to the sympathetic.

The case of thoracic "cyst" was distinctly in its appearance like those which have been described as instances of circumscribed serous meningitis. It was localized by hypalgesia, the upper limit of which was two or three inches above the umbilicus. Severe and persisting pain both in the back and in one of the lower extremities at first without and later with complete paralysis in both extremities, exaggerated reflexes, including the Babinski response, with bladder and rectal involvement, were the most marked manifestations. After evacuation of the cyst the pain was for a time relieved, the patient recovered the use of his limbs so that at first coarse movements and afterward the movements of the toes could be performed. He suffered, however, from serious cystitis and delirium, probably dependent on toxemia. He made what might be termed a partial recovery, but relapsed.

In the third case, that of sarcoma of the cauda equina and lumbosacral roots, the early manifestations were pain of an extremely severe character, which affected the back and the extremities first on one side and then on the other. In this case the anesthesia which developed indicated involvement of the posterior nerve roots, at first of the conus and later of roots higher up, as high as the second lumbar. They were distinctly root areas, not segmental or of the extravertebral neural type. The patient eventually was completely paralyzed, with marked atrophy, paralysis of the sphincters, and the whole train of phenomena showing destructive implication of the nerve roots originating from the lumbosacral spinal cord. The cord itself was also apparently involved by pressure or extensions of the lesion.

DISCUSSION

DR. W. G. SPILLER, Philadelphia: The case of circumscribed serous spinal meningitis reported by Dr. Martin, Dr. Musser and myself was the first of its kind reported. The patient is now in perfect health, except that she occasionally has a little pain in the back, possibly from catching of some fibers. There is no possibility of diagnosing a circumscribed serous meningitis from a tumor. As Oppenheim has pointed out, there will be variation with the fluctuation of the fluid in the dural canal.

DR. G. JACOBY, New York: I present two specimens. One was taken from a man who suffered with symptoms of gradually increasing pressure paralysis and paresis and disturbance of sensation for a period of ten or twelve years. He was able to walk to the hospital but had marked weakness of both lower extremities. There was sufficient sensory disturbance to enable us to make a diagnosis of probable intraspinal tumor at the sixth dorsal vertebra. At operation we found at this sixth dorsal segment an enchondroma growing from the body of the vertebra into the spinal canal compressing the cord so that the cord was attenuated to simply a filament. The second patient was operated on by Willy Meyer and a glioma removed from the cord substance. In this case the entire history of disease was only three months. The first symptoms were weakness of the lower extremities which progressed so that there was spasticity and paraplegia and all the symptoms of complete pressure paralysis of the cord. The tumor in this case was the size of a large cherrystone.

DR. G. L. WALTON, Boston: With regard to the level of anesthesia as determining the position of the spinal tumor, one very practical point is to be borne in mind, namely, that the accumulation of fluids, whether in the cord itself or in the membranes, is likely to produce symptoms which may be erroneously credited to the tumor itself. It is true that in the majority of cases the point selected for operation should err in the direction of being set too high rather than too low. But, if we always follow this plan, we may be misled, as in a case in which I recently had occasion to advise operation. In this case severe pain in the lower back and extending down the thighs was rapidly replaced by paraplegia with numbness extending nearly to the umbilicus. Finding it hard to credit the tumor itself with such rapid growth I was guided rather by the initial pain, and advised removing the tenth and eleventh dorsal laminæ. Operation at this point disclosed the upper limit of the tumor, above which the cord was apparently normal. If the cord had been exposed at the level indicated by the level of anesthesia, its normal appearance would have led to the erroneous conclusion that no tumor existed. I am inclined to credit accumulation of fluid with the rapid extension of symptoms.

DR. J. J. THOMAS, Boston: I agree with Dr. Spiller in reference to diagnosing circumscribed serous meningitis from tumor. In regard to the point of differential diagnosis between growths of the spinal cord, whether from the pia or dura, I confess that I have less confidence in our ability to differentiate them exactly. In the case that Dr. Walton referred to I was rather opposed to operation because of the intense character of the symptom, coming on suddenly, which seemed to him to point to total destruction. Within two or three days the man became completely paralyzed in both sensation and motion.

DR. H. T. PATRICK, Chicago: The upward movement of the umbilicus when the patient, lying with his arms folded across his chest, raises his head from the pillow, known as Beevor's sign, is of service in diagnosis in spinal cord tumors. The recti muscles are not paralyzed but the muscles below are paralyzed and the umbilicus makes an excursion of a half inch or even more.

DR. E. JONES, Toronto, Canada: I was Dr. Beevor's assistant for a few years and I would add two points to what has been said of Beevor's sign. In some cases you will get it obliquely, not only drawn upward, as one of the muscles is paralyzed below, but sometimes obliquely to the right or left which gives a clue to the side of the tumor. Further, in cases of congenital dystrophy with paralysis the umbilicus is drawn downward.

DR. M. A. BLISS, St. Louis: I have had quite a distinct case of circumscribed serous meningitis. A laminectomy was done, then a second laminectomy, when an endothelioma was found.

DR. C. K. MILLS, Philadelphia: I am not altogether satisfied with the term circumscribed serous meningitis or with the explanation which is involved in the use of this term. In the case which I reported I think it quite possible that there was more than was apparent. The probabilities are that there is a universal serous meningitis and possibly chronic meningitis with, perhaps, two or three pockets where cystic foci appear, as in the present case. The differentiation between intrapelvic and spinal tumors can usually be made. We simply have not been careful enough.

Fracture of the Bodies of the Fourth, Fifth and Sixth Cervical Vertebræ with Injury of the Spinal Cord

DRS. W. H. SWAN, Colorado Springs, C. A. POWERS, and H. T. PERSHING, Denver: A man, aged 70, fell from a horse, striking on his forehead. There was immediate motor and sensory paralysis below the neck with evacuation of bladder and bowel, without loss of consciousness. Extreme shock, followed for some months by improvement, without restoration or ability to stand, sit alone, or turn in bed. Daily catheterization was done with no ill effects. Eczema which was present rapidly disappeared on the anesthetic skin up to a sharp line of demarcation, then slowly cleared above. There was greater mental activity and happier mental state during about 18 months than before injury, probably due to relief from unpleasant sensations. Death took place 28½ months after injury from uremia. Operation was considered and rejected on account of patient's age and the improbability that a remediable lesion would be found. Fixation of head was deemed inadvisable. The dried preparation of the cervical spine of this patient shows no lesion of the arches or articular processes but a moderate crushing of three bodies which could not have been remedied by operation. Localization diagnosis was based on retention of power in deltoids and biceps with paralysis of both triceps muscles which indicated a lesion of the seventh cervical segment. Faradic tests indicated almost complete escape of anterior gray horns and anterior roots. Autopsy showed the bodies of the fourth, fifth and to a lesser extent the sixth cervical vertebræ to have been fractured by a crushing force but the fragments united in normal position. The arches and articular processes showed no injury. Preliminary histologic examination shows the usual ascending and descending degeneration.

DISCUSSION

DR. H. N. MOYER, Chicago: This case follows the general rule that the fifth cervical is the most frequent seat of these cervical fractures. So far as operation is concerned, this case rather favors operation. The value of operation in these cases is unquestioned. The distinguishing features for the neurologist is to understand if there is extrinsic pressure. The hematomyelia is not, of course, to be operated on. I do not wish to be understood as saying that this old man of 70 ought to have been operated on. I am speaking of the broad general principle of operation. I believe it to be a sound rule to fix the cervical vertebræ where you have a fracture if you don't operate. In all the cases I have seen I have recommended fixation.

DR. H. T. PERSHING: When it comes to a question of operation in a case of this kind you have to consider the individual patient and the advantage of accomplishing anything. In this case, of course, we could not have reached the seat of fracture in the bodies and done anything with them. The risk from the operation *per se* is very great and, of course, with this particular man would have been very much greater. There were many things aside from his age which made it necessary to be very cautious about operation. The question of fixation was discussed very carefully and very earnestly and it was decided in the negative, mainly on account of the absence of rigidity and pain; the disposition of the patient after being warned was to keep his head still on the pillow. Also because of his temperament it would have been very difficult to make him submit to fixation.

(To be continued)

NORTH DAKOTA MEDICAL ASSOCIATION

Twenty-third Annual Meeting, held at Grand Forks, May 10-11

Under the Presidency of DR. J. E. COUNTRYMAN

Officers Elected

The following officers were elected: President, H. H. Healy Grand Forks; secretary, Dr. H. J. Rowe (re-elected), Casselton

Benefits of Organization—President's Address

DR. J. E. COUNTRYMAN: So many members of the professio do not appreciate the many advantages of a meeting of thi kind, where for the time being we can lay aside the cares o the profession, where we can absorb knowledge, one from th other, get new ideas, rub elbows with the other fellow and g home with new incentives to do better work and accomplis greater things. When a physician thinks it unnecessary t belong to his district society or to take some interest in th affairs of his state organization, or, in short, thinks there i nothing further for him to learn, then he is unable to mak such use of his talents as should be expected and demanded c him by his patients. During the past year we were favore by a series of addresses from Dr. J. N. McCormack of Bowlin Green, Ky. His remarks were timely and will be productive c much good, and the thanks of this Association are due to hi and also to the American Medical Association, under whos auspices it was made possible to carry out this line of wor I particularly wish to call your attention to the subject medical legislation. We have reached a period of our grow when we must reach out for that, which under all rules right and justice, must be considered our due. The medic profession is great enough to secure the passage of just law if you will only make up your mind that it is an individual well as a collective work by the members of this society. W must get into practical politics. In addition to a new law f the Board of Medical Examiners, we particularly need a ne State Board of Health law.

A great deal of interest has been manifested throughout t state during the past year in preventive medicine. The wo of the Anti-Tuberculosis Society and the Public Health League is to be especially commended and such work can not fail to impress the public at large that the medical profession is interested in their welfare other than from a mercenary standpoint. A wide spread interest on the part of the profession generally in work of this kind will do more than any other agency to remove antagonism to needed legislation.

Owen Bill

The Owen Senate Bill 6049, providing for the establishment of a Department of Public Health was heartily endorsed, and representatives in congress were urged to use their best efforts to secure the passage of the bill.

Official Journal

The committee on the publication of a medical journal reported that no feasible plan had been found that would give the association a creditable publication at present, and recommended that action be deferred but that investigations be continued with a view of finding plans by which a state publication can be had that would be a credit to the Association.

Education of Public on Health

The following resolutions were adopted and sent to the Superintendent of Public Instruction:

WHEREAS, Health officers and physicians generally encounter antagonism to the proper enforcement of sanitary laws and regulations, owing to the lack of knowledge in hygienic matters on the part of the laity, and

WHEREAS, Many diseases, in the light of present day scientific knowledge, are often unnecessarily transmitted from one person or place to another, and

WHEREAS, In our opinion the best place to disseminate and popularize the knowledge necessary to prevent preventable disease is the public school; be it

Resolved, That preventable diseases should be taught more extensively in our schools.

Public Health Leagues

The Committee on Public Health reported that public health leagues had been organized in a number of places throughout the state and that there was considerable interest manifested in the discussion of tuberculosis, water supply and typhoid fever, sanitation with special reference to water and milk supplies, contagious diseases, insects as carriers of disease, the importance of having a clean city, medical inspection of school children, scarlet fever, the visiting nurses, etc.

Serum Disease or Serum Anaphylaxis

DR. G. F. RUEDIGER, University: Serum disease, as manifested in man, and serum anaphylaxis observed in experimented animals seem to be one and the same reaction. The intensity of the reaction depends on the sensitivity of the person or animal receiving the injection, on the size of the dose and to some extent on the serum injected. Certain precautions should always be observed in the injection of base serum into man. Where there is a history of asthma or of a previous injection of horse serum, the danger should be explained to the patient and friends. Except in urgent cases, a small quantity, such as 0.5 c.c.. should be injected for the initial dose, waiting several hours before a second injection is given. This is to allow the immediate reaction to take place, which, if there will be such a reaction, would be less severe after a small injection than after a large one. After recovering from this reaction more serum can be given with safety. The required amount of antitoxin should always be given in the smallest possible bulk of serum. All the serum required in a case should be given within a short space of time so as not to allow time for hypersensitivity to develop.

Legislative Advances

PROF. E. F. LADD, State Food Commissioner: I believe that through the workings of our food, drug and sanitary laws, something has been accomplished which will be of benefit to preventive medicine, that our people are better nourished now, that flagrant food adulteration is no longer tolerated; that chemical preservatives or germicides are not permitted; that saccharin is not allowed as a sweetening agent in place of sugar; that our meats are no longer embalmed with sulphites or borates; that formaldehyd finds no place in our daily supply of milk; that many badly decomposed products only fit for the crematory are no longer prepared for the table of our laborers; that our beverages are now coming to be more nearly what they are represented to be; that substitution in both imported and domestic drugs is no longer practiced; that drugs must be true to name and of proper strength; that many fake remedies have been exposed and the people shown their true value; that our food supply is better taken care of under our sanitary laws; that food products are not now exposed, unprotected, to the germ-laden dust and filth of the streets; that it is fast becoming a disgrace to tolerate flies where food products are handled and merchants and dealers are protecting their places against the intolerable nuisance of flies, one of the greatest disease distributors of our time. There is no question that cold storage is a most desirable means of preserving for a limited space of time articles of food, but the introduction of cold storage and its monopolization by a few has brought about conditions which may have had an unfavorable influence on the nourishment and health of our people. The use of chemical preservatives in food products is an old question, but nevertheless, it continues to be prominent in the public mind for the reason that there are those who are persistent in using certain classes of chemical preservatives or antiseptics in various food products, while, at the same time, there are others putting up and selling the same class of products without the use of preservatives of any kind. It is now almost universally conceded that the use of formaldehyd is dangerous; that the use of boric acid or hydrofluoric acid is not to be commended; that salicylic acid should be condemned; that sulphurous acid of sulphites should not be used in meats, candies, corn, etc. The general sentiment of those who have studied the matter most thoroughly is that the use of benzoate of soda, sulfurous acid and saccharin is not to be commended and that their use should not be permitted in food products to be used indiscriminately by the general public.

The general consensus of opinion, on the part of the physicians throughout the state, is that preservatives of all classes in food products, beverages, etc., should be discouraged. Drugs differ from food in that drugs and medicines modify some vital action but do not supply food material to sustain that vital action, it is hard to understand how we can endorse the use of drugs in foods and beverages, which drugs are generally employed in medicines. The human body is not a mere machine unacted upon by the material which passes through it. The cells of the human body are living protoplasm, sensitive to the same influences which would destroy the protoplasm of bacteria or micro-organisms. How can we then logically reason that poisons, antiseptics, germicides, which will destroy bacterial protoplasm, shall in no way modify or effect the tissues of the living body, the most highly organized of all protoplasm.

The consensus of opinion of the North Dakota physicians as set forth in Special Bulletin 14 shows that 157 out of the 171 physicians reporting would not allow the use of chemical preservatives such as are named in any article of food; 163 out of the 171 would, under no condition, permit of the use of benzoate of soda in foods which are intended for the use of invalids or infants. In fact, there was only one physician of the 171 who would permit of the use of benzoate of soda in food products unrestricted, and leave it to the public to determine whether or not they desired to purchase the article. Unfortunately, there are found in nearly every large city men who have in some manner secured the degree of M.D. who are either failures in the practice of medicine and so turn to quackery and fraud, or have purposely adopted this easy method of securing money by preying on unfortunate sufferers or on those who are easily misled and made to imagine that every little ache or pain is to be nursed until life to them is almost unbearable. If the medical association of each state had a committee to look after matters of this kind, it would not be long before society would be rid of these *despicable* specimens of humanity who are bringing discredit on the noblest profession of our fair land.

Other Subjects Discussed

The papers submitted were varied and of scientific value and the topics provoked much discussion which was participated in by many of the practitioners. The discussion of the medical practice act was intensely interesting and while there was divergence of opinion as to how it could best be attained, yet the unanimity in the purpose of getting together to accomplish the end sought was the crowning feature of the debate.

AMERICAN SURGICAL ASSOCIATION

Annual Meeting, held in Washington, D. C., May 3-5, 1910

(Continued from page 47)

Tests to Determine Efficiency of Collateral Circulation Before Attempting Permanent Occlusion of Large Arteries.

The points covered in this paper by Dr. R. Matas, New Orleans, are contained and elaborated on in a paper read in the Section on Surgery of the American Medical Association, and which will be published in The Journal.

Case of Hepatico-Duodenal Anastomosis

Dr. George Emerson Brewer, New York: The patient was admitted to the hospital suffering from acute cholecystitis. Following a cholecystectomy, there occurred extensive sloughing of the wound and a complete biliary fistula. At the end of 75 days, as no bile was passing into the bowel, the abdomen was reopened and the fistula followed down to the common hepatic duct. As no trace of a common duct could be found, even after reflecting the duodenum and exposing the head of the pancreas, it was assumed that it had been destroyed by the suppurating process which followed the primary operation. A rubber drainage tube, three inches in length, was introduced into the hepatic duct and also through the duodenum by a stab wound at its upper border, and was secured in these two situations by two purse-string sutures. A mass of omentum was then wrapped around the tube, extending well beyond its introduction in the hepatic duct and duodenum, with a view to create a new common duct, after the manner suggested by Sullivan. The abdominal wound was closed, a small cigarette drain being allowed to remain at its upper angle. From that time no bile appeared in the wound. The bowels moved on the third day as the result of an enema, and the stools contained an abundance of bile. The reconstructed duct continued to functionate until after the man's discharge from the hospital, some four or five weeks after the last operation. Since then he has had two or three attacks of fever, associated with jaundice, which would disappear in two or three days. At the present time he is still jaundiced, although some bile is present in the stools.

Dr. Alexander H. Ferguson, Chicago: Since the observation that if all the bile is directed into the hepatic flexure of the large bowel the patient does not suffer from the lack of bile, I have followed this technic in at least half a dozen cases with extremely gratifying results.

Dr. Joseph C. Bloodgood, Baltimore: I wish to report an anastomosis of the small intestine by opening the transverse colon as in posterior gastroenterostomy, sewing a long loop of the small intestine through the transverse colon, and suturing it to the gall-bladder.

Case of Resection of Pancreas

Dr. J. M. T. Finney, Baltimore: I wish to record the successful removal of a primary solid tumor of the pancreas. The operation involved the resection of the entire middle portion of the gland, leaving only a small piece of the head and the tail, respectively, and necessitating a reunion of these segments by suture. The statistics of the operation for primary tumor of the pancreas are as follows: Of the 17 cases recorded in the literature 12 occurred in females and 5 in males. Carcinoma occurred 10 times, sarcoma 4, fibroadenoma 2, cystic adenoma once. Of the 17 patients 9 recovered and 8 died. In two instances the pancreas has been reported as having been removed *in toto*. Three times the gland was completely divided into two parts and the remaining portion sutured. All three patients recovered

DISCUSSION

Dr. M. L. Harris, Chicago: A policeman was shot by a 38-calibre bullet which entered just below the twelfth rib on the left side and was found just beneath the skin a little to the right of the median line between the eighth and ninth ribs. The track of the bullet was from before backward through the right lobe of the liver, the lesser curvature of the stomach, the middle of the pancreas, practically bisecting the organ, and the left kidney. The stomach was sewed up, then the pancreas, and as close an approximation of parts made as possible. Drainage front and back. A fistula resulted, but closed in about three months and the patient fully recovered.

Dr. Willy Meyer, New York: I have had two cases in which the tail of the pancreas was tightly adherent to the existing tumor, and here I put a piece of chromicized gut around it and divided the distal end with the Paquelin cautery. Both patients recovered.

Dr. Rudolph Matas, New Orleans: I wish to report a cause of thrombosis of the splenic artery involving the pancreatic arterial supply, causing degeneration of the organ from the head to the tail, associated with multiple tumor formation in the spleen. The spleen and three-quarters of the pancreas were removed and the patient recovered from the operation, dying about three years later from a slow fever.

Congestion of the Lower Lobe of the Right Lung an Early Symptom in Appendicitis

Dr. John B. Roberts, Philadelphia: There is a possibility of a secondary congestion of the lower part of the right lung in a considerable number of cases of acute appendicitis in its early stages. This condition may be a possible aid in the diagnosis of acute appendicitis when the symptoms of the latter are not yet very definite. Appendicitis, and perhaps other intra-abdominal inflammations, may cause atelactasis of the right lung, or a true congestion, because of the insufficient action of the diaphragm on the right side. The early congestion of the right lung, which is found in the early stages of appendicitis, might also occur from inflammation of the gall-bladder or cellulitis around the upper pole of the kidney.

Vaccine Therapy as an Adjunct to Surgery

Drs. John B. Deaver, John C. Da Costa and D. B. Pfeiffer, Philadelphia: In addition to its well-known and satisfactory use in suppurative affections of the skin and other forms of minor chronic infection, this form of treatment has been used as an adjunct in the treatment of more severe surgical infective conditions. Vaccines did not prove of service in three cases of streptococcic septicemia in which the treatment was begun late. Four patients with severe staphylococcic septicemia recovered, improvement in each case beginning with the iniation of the vaccine treatment. Eight patients with severe septic intoxication without demonstrated bacteriemia were treated by drainage and vaccines. Two were *in extremis* when treatment was begun and died shortly afterwards. The remainder recovered. Five of the cases were streptococcic infections.

Improvement was also noted in a miscellaneous group of cases comprising persistent sinuses, cystitis, thrombosis, etc. Not all cases, however, gave a definite response. The dosage varied from 25,000,000 to 750,000,000. The sicker the patient and the less satisfactory the response, the smaller and less frequent should be the dose. Streptococcus also was used in smaller dosage than staphylococcus. Specific vaccine treatment has not proved of benefit in the later stages of streptococcic septicemia. Staphylococcic septicemia has been treated with most favorable results at all stages. Septic intoxications without demonstrated blood invasion in a majority of the cases display general and local improvement under the use of vaccines, if given early; the later the treatment, the less certain and satisfactory the result. Localized and persistent suppurating lesions are sometimes markedly benefited by vaccines. Surgical procedures for the relief of infectious conditions should be reinforced by vaccine treatment, which should be begun as early as is consistent with the case, and preferably by autogenous organisms.

Therapy by Bacterins and Tuberculins in Mixed Suppurative Bone and Joint Disease

Drs. DeForest Willard and B. A. Thomas, Philadelphia: We have now had two years of experience in the treatment by bacterins of tuberculous bone and joint diseases, complicated by mixed pyogenic infections. The feature of the treatment consists in the alternation of bacterin and tuberculin inoculations in the mixed suppurative type of the disease, as spinal caries, tuberculous hip-joint disease, etc. We do not contend that bacterin therapy is a "cure all," nor that when indications for surgical intervention exist, they can be disregarded and active immunization substituted. However, the accessory employment of bacterin and tuberculin in certain cases stimulates the tissue cells of the organism to the production of specific antibodies to assist the bodily defenses in antagonizing and combating the given infections. Bacterins, particularly tuberculin, are invaluable aids in competent hands, and when so treated such patients do better than those treated without bacterins; their detention in the hospital is shortened, and complications, if they occur, are fewer and less severe. Studious observations of the clinical symptomatology have always sufficed to control the treatment, the opsonic index proving not only impractical, but unreliable.

DISCUSSION

Dr. J. M. T. Finney, Baltimore: In a case of chronic colon bacillus infection of the bladder, after every other method had failed, injections of vaccine were followed by the most astonishing results, the bladder symptoms all practically disappearing.

Dr. George M. Sternberg, Washington: It is impossible to doubt that vaccine treatment is beneficial in a certain class of cases, but it is difficult to understand why it should be. You have a certain specific microorganism in the blood in large numbers producing toxic products, and why the introduction of a comparatively small number of the same microorganisms under the skin should have such a potent effect in arresting the progress of the disease is inexplicable.

Dr. L. L. McArthur, Chicago: Treatment with the autogenous vaccine of the colon bacillus in several cases of essential hemorrhage from the kidney has been productive of a cure, and I consider this a most beneficial treatment in this condition.

Dr. John B. Murphy, Chicago: Essential hemorrhage of the kidney and essential hemorrhage of the uterus occurring in girls under 20 with tuberculous histories respond marvelously to proper dosage with tuberculin. Great assistance is rendered by this treatment in cases of bone tuberculosis. As a stimulant, and as an aid to surgical tuberculosis, I know of nothing so good when the treatment is carefully administered.

Dr. Joseph A. Blake, New York: I have been employing the vaccine treatment in chronic infections and have found the autogenous vaccines of great benefit.

Dr. Arthur Dean Bevan, Chicago: I have been particularly interested in the application of the vaccine treatment to tuberculosis of the kidney and mixed infection of tuberculosis of the colon, and, although I know of patients who under good management with this treatment have gone on to recovery, I know of patients who recovered without the vaccine treatment.

Dr. Francis B. Harrington, Boston: I have seen some cases in which autogenous vaccines have been of great benefit, and also some cases in which they were productive of great harm.

Dr. Harry M. Sherman, San Francisco: With regard to the vaccine treatment, we have had no success with the streptococcus infection.

Dr. Emmet Rixford, San Francisco: I wish to mention a patient with tuberculous anal fistula, tuberculosis of the spinal cord, and tuberculosis of the wrist, who under treatment with tuberculin was completely restored to health. It has been two years since the treatment. There is now no sign of tuberculosis, and the patient has gained 40 pounds in weight.

Dr. James E. Moore, Minneapolis: I have been disappointed in the serums for the treatment of acute infections. In tubercular cases I have had better results. It is very essential that these treatments should be carried out only by those who know how to use them.

Dr. Charles H. Mayo, Rochester: I have had very little experience with the vaccine treatment, but I have had one case of colon bacillus infection of the bladder and kidney in which the autogenous vaccine proved of benefit.

The Etiology of Cancer Based on Clinical Statistics

Dr. Isaac Levin, New York: My investigations are based on a clinical study of 4,000 cases of carcinoma and sarcoma collected from several large hospitals in the country. The greater frequency of the disease in women is due to the prevalence of cancer of the uterus and the female breast. The other organs become affected more frequently in men, which fact may be due only to the greater subjection of the latter sex to the different injurious influences of civilized life. Cancer, while considered to be a disease of an advanced age, appears, according to this investigation, to occur in many instances in people who have not yet reached middle age. Child-bearing does not seem to have any direct connection with the causation of cancer. Another point of interest is the fact that American Indians rarely contract the disease. The data on the influence of occupation in the etiology of the disease were very defective and no conclusion could be derived from them. The presence of a preceding local disease in the organ affected with cancer, while of certain importance, cannot be considered as the main etiologic factor. Hereditary disposition does not seem to have an influence on the causation of the disease sufficient to warrant the great dread of the lay public before this hereditary trait. It appears evident that a local trauma or previous disease of the affected organ is of less importance in the causation of cancer than the increased vulnerability and lessened resistance of the organism caused by the ever increasing strain of modern life. This is certainly the only explanation that may be offered for the increasing frequency of the occurrence of cancer in civilized communities.

Review of One Hundred and Twenty Resections of the Rectum for Cancer

Dr. William J. Mayo, Rochester, Minn.: The ages varied from 27 to 81 years. There were done by the perineal route 38 operations, by the posterior route 56 and by the abdominal route 26 operations. Three deaths occurred from exhaustion more than four weeks after operation, one from pulmonary embolus, and one from apoplexy. The mortality in the whole series of 120 cases was 20.16 per cent. Four patients are alive and well after 5 years; 13, after 4 years; 63, after 2 years; 102, after one year, and 18 out of 82 operated on less than one year ago.

DISCUSSION

Dr. Arthur Dean Bevan, Chicago: After an experience in some 20 cases of the Kraske operation, we do not employ a single ligature. As we come to the tissues on the sides of the incision freeing the rectum, massive 10-inch or 12-inch clamps are put on the tissues. With the employment of these clamps there is less risk of hemorrhage and a greater saving of time than if an attempt is made at ligation.

Dr. Joseph C. Bloodgood, Baltimore: One of my first cases (operation about six years ago) was such that we were able to save 3 inches of the anus and rectum, making a suture of the sigmoid which was brought down, and this patient is well and has perfect function.

Dr. Alexander H. Ferguson, Chicago: In some of these cases I have resorted to the combined operation in two stages to advantage. Open the abdomen, take the proximal end of the bowel, make an artificial anus, invert the distal end into the rectum—that would be one operation; then, when the patient is in good condition, remove the rectum from below, the bowel being already inverted giving ready access to the mass. By the use of clamps without ligatures the operation can be done in a few minutes.

Dr. Joseph A. Blake, New York: I have had more experience with the combined operation than with any other. I have done 12 consecutive operations without any mortality. The mortality is less, if a permanent colostomy is done.

Dr. G. E. Armstrong, Montreal: In the low cases in which the sphincter has been involved I have sometimes succeeded in getting a satisfactory sphincter by bringing the upper ends down through the lower fibers of the gluteus maximus. One patient operated on ten years ago now has perfect control.

Case of Choriocarcinoma Occurring in a Patient with an Infantile Uterus

Dr. A. Primrose, Toronto: The tumor removed presented the characteristic elements of a choriocarcinoma with a very large proportion of Langhans' cells showing metaplasia and mitosis. A few isolated masses of the syncytium were also present.

Prognosis and Operative Treatment of Fracture of the Base of the Skull

Dr. Joseph Ransohoff, Cincinnati: Of 190 cases occurring during the last ten years in the Cincinnati Hospital, 124 were fatal. Of 42 patients with non-reacting pupils, 41 died. In 5 years there were 19 operations, trephining or decompressive, with 7 recoveries. There will always be a large mortality connected with basal fractures; death resulting from primary shock, brain laceration or hemorrhage. Thirty-seven per cent. of the fatal cases end within 6 hours or less and 56 per cent. end within 12 hours. It is not probable that the mortality of this class of cases can ever be reduced with or without operation. They are primarily fatal. Twenty-three per cent of the fatal cases end during the second day. They are the cases in which the coma is not profound; in which the pupils are not fixed; in which the breathing is not stertorous and in which there is not complete muscular relaxation. With a slow full pulse and lumbar puncture, indicating hemorrhage and increase of intracranial pressure, a trephining operation is indicated. In the doubtful cases an operation is indicated. In this class of cases, where facilities for the major operation of trephining are not at hand, repeated lumbar puncture should be essayed. This procedure may be destined to take the place of decompressive operations. There is a large group of cases in which there is complete consciousness or in which there is a somnolence or milder degree of coma, and in whom the concomitant symptoms do not indicate a grave intracranial trauma either to the brain or its vessels. The pupils, though uneven, react; involvement of one or more cranial nerves may be evident. The symptoms singly or collectively are not ominous at any time. Eighty per cent. of this class of cases have a tendency to get well with or without operation. The patients should not be operated on unless the symptoms indicate an increase of intracranial pressure from hemorrhage, beginning cerebral edema or distinct localizing (cortical) symptoms. There is a distinct class of cases in which operation is indicated. There are cases which, seemingly not severe in the beginning, grow progressively or suddenly worse, showing signs of increased intracranial pressure. Decompressive operations may save a considerable proportion of them. It has yet to be determined where the trephining should be done to obtain the best results. Since most fractures involve the anterior or the middle fossa, subtemporal trephining is doubtless the procedure oftenest indicated. When, however, an hematoma in the mastoid or occipital region indicates an involvement of the posterior fossa, the operation should be subtentorial. To relieve the subtentorial tension by an opening made in the temporal region is illogical and may be dangerous. I attempted it recently in a cerebellar tumor, the site of which could not be determined. The patient succumbed within two weeks with symptoms of bulbar paralysis.

Dr. Frank E. Bunts, Cleveland: In an ordinary case of fracture of the base of the skull in which the blood pressure can be obtained, a beginning choked disc and edema and hemorrhage in the brain are detected, the decompression operation should be performed, and in many such cases we may expect altogether beneficial results.

Dr. G. E. Armstrong, Montreal: If in these cases the pressure is substantial, as indicated by the respiration, aspiration of the cerebro-spinal canal may prove very injurious.

A Method of Overcoming the Shortening in Old Fractures Treated by the Open Method

Dr. Edward Martin, Philadelphia: The method consists in using a long, strong canvas strip pocketed in the middle and looped at the ends. The bones at the seat of fracture are freed, the pocket is slipped over the proximal end of the distal fragment, the ends of the canvas strip are carried in the long axis of the limb, and in the loops is fixed a cord to which are attached the weights. By thumb pressure the bone is kept from angling out of the wound, and weights up to 100 pounds or even more, are attached to the rope. In from three to five minutes the shortening is overcome. Only those structures which interfere with proper placement are stretched, and this is done so thoroughly that there is but slight tendency to the reproduction of deformity.

Dr. Richard H. Harte, Philadelphia: A pulley similar to that used on boats, a double and single pulley, is the best type of extension. These should not be close together, but enough line between them to allow of manipulation of the limb by the operator. After the ends of the bone are exposed, disengage the bands of tissue by the employment of steel elevators. It is important to do as little damage as possible to the tissues. I do not consider silver plates strong enough to hold the bones in position and therefore would always advise the use of a heavy steel plate, such as that suggested by Lane.

Dr. Albert J. Ochsner, Chicago: A method which we use almost entirely consists in the slow stretching of the muscles, instead of the rapid stretching, and the only thing that is peculiar about the method is the application of rubber adhesive strips to as high a point above the seat of fracture as is possible. For instance, instead of applying the rubber adhesive up to the fracture, it should be applied over the entire length of the thigh, then, with no more than 24 pounds of weight, we have, in every fracture where there has not been a union, been able to stretch the muscles sufficiently to replace the fractures without making a resection of the ends. In cases in which there is a union in malposition the muscles will stretch to a marked extent. It is important to use two Lane plates with two screws at each end in order to keep the bones from slipping.

Dr. Harry M. Sherman, San Francisco: I use two hanks of yarn applied as perineal straps, the weight coming on the tuberosity of the ischium. On the foot is put another hank of yarn. The pulling on the bones has been measured, and over 200 pounds of weight have been applied in some cases without injury to the ligaments of the ankle or knee, and that is sufficient to pull out any tissue interfering with the approximation of the bones.

Fracture Dislocations of the Os Innominatum

Dr. Harry M. Sherman, San Francisco: Simple uncomplicated fracture of the pelvic bones is not of necessity a serious lesion, and healing can be expected in an ordinary way as after a fracture of a bone of an extremity. The really serious lesion is the complication of injuries to the bladder, the intestines or the vascular system. Injuries to the bladder are more likely to occur when the fracture has been due to antero-posterior compressive force. Injuries to the urethra are more apt to occur when the fracture was due to transverse compressive force. The present indications are to open at once the space of Retzius and make a reverse catheterization and perineal section with lateral incisions in the groin and perineum for drainage of all areolar planes. With this technic the mortality should be reduced to about 33 per cent. as against 60 per cent.

Dr. Arpad G. Gerster, New York: I have had a case of fracture of the female pelvis on the left side in which there was no injury to the urethra, although it was compressed to such an extent by a solid blood clot that retention followed and had to be relieved for 15 or 16 days by the use of the catheter. There was no other injury present and the woman recovered. Another case was one in which there was fatal hemorrhage following fracture of the pelvis. Postmortem revealed extensive laceration of one of the common iliac arteries and subperitoneal hemorrhage.

Momburg's Method of Artificial Anemia by Suprapelvic Constriction

Dr. Arpad G. Gerster, New York: The method consists in the application of the Esmarch principle to the waist and to the abdominal aorta, which thus, by the superposition of from two to six turns of the elastic cord, is compressed against the lumbar spine. The apprehension that the necessary amount of constriction might damage the gut has not been justified by experience. The interruption of the aortic blood current is regularly followed by a marked rise of the blood pressure and its restoration by a still more marked cardiac depression, which, in patients afflicted with arterio-sclerosis, myocarditis, or even well compensated valvular lesion, may attain alarming proportions. Hence, Momburg's method is not suitable in these cases. In healthy and young individuals, however, its use is free from danger. The method's greatest utility for life-saving has been demonstrated in postpartum hemorrhage, where it affords the advantage of an easy and prompt control of the loss of blood.

Dr. Joseph Ransohoff, Cincinnati: I have seen this method pursued in one case, and in this no ill effects resulted from its employment.

Dr. Rudolph Matas, New Orleans: I have pursued some experiments among students with this method, but found that a fair test of it could not be made unless the patient was anesthetized in order to gain complete relaxation. From our very imperfect experiments, however, it was shown that in all weak hearts you are liable to have prompt failure; instead of noting the usual increase in blood pressure, there will be a fall, and this, we feel, indicates an inability on the part of the heart to keep up. I would not advise the use of the Momburg constrictor in any patients suspected of having any cardiac irregularity, but believe it will prove of great benefit in producing artificial anemia in strong, robust individuals without being followed by any ill effects.

Operative Treatment of Tumors of the Hypophysis

Dr. A. E. Halstead, Chicago: The routes of approach previously advocated have been the intracranial and the extracranial. I propose what I term the oro-nasal route, which I employed successfully in one case. It is a modification of the infranasal method of approach, but is without the trauma and disfiguration which must follow the König operation.

DISCUSSION

Dr. S. J. Mixter, Boston: I wish to present a case operated on by the route suggested by Kanavel. There was a large cyst in the hypophysis filled with cholesterin and holding about one and a half to two ounces of fluid. The patient made a good recovery after the operation and his vision, which before was extremely poor, has been benefited.

Dr. Harvey Cushing, Baltimore: The various means of approach to the hypophysis do not make so much difference as does the matter of dealing with the structure when it is brought into view. The growth often becomes malignant, as is true of long-standing trouble with the thyroid, and it is conceivable that it cannot be removed entirely. In fatal cases it has often been found that only a mere fragment of the growth has been taken away. The operation, in the first place, has for its object the relief of pressure; the symptoms can be combated by the mere removal of the lower part of the sella turcica and the splitting of the capsule of the gland.

Dr. A. B. Kanavel, Chicago: Concerning the technical procedure in Dr. Halstead's cases, in the first one particularly, the view could not have been better. The operation was very quickly done, the anterior wall of the sphenoid sinus quickly removed, the bulging sella turcica opened, and a tumor protruding into the sinus was removed without difficulty. In the second case the sella turcica did not bulge into the sinus; it was seen with more difficulty and was arrived at by anatomic deductions. In two cases there was considerable hemorrhage, and I would suggest the elevation of the head during the operation. In the majority of cases it will only be necessary to remove the vomer and the anterior portion of the sphenoid in order to come down on the sella turcica.

Benign Bone Cysts, Osteitis Fibrosa; Giant-Cell Sarcoma and Bone Aneurism of the Long Bones

Dr. Joseph C. Bloodgood, Baltimore: The so-called benign bone cyst may present itself in five forms: First, as a medullary cyst without any definite gross lining; second, as a similar cyst with a definite connective tissue lining which is easily stripped from the bony capsule; third, as a medullary mass of fibrous tissue with a small cyst; fourth, as the same medullary mass of fibrous tissue without any cyst formation; and, fifth, as multiple medullary cysts. Among 89 cases on record 69 belong to the variety of true localized bone cyst or osteitis fibrosa. The other 20 cysts have different etiologic factors; for example, cysts in enchondroma, in pure myxoma, in giant-cell sarcoma, in osteitis deformans; cysts due to subperiosteal ossifying hematoma, and callous cysts. The so-called bone aneurism is a much less frequent tumor and is distinctly malignant. It is a hematoma due to hemorrhage in the most malignant form of medullary, spindle, round or mixed-cell sarcoma, and I am of the opinion that in this stage of this tumor metastasis has already taken place, so that no harm could come from mistaking such a tumor for a bone cyst or giant-cell sarcoma. I have seen three cases, one of which was not saved by the highest amputation; in the second case amputation was refused; the third case was first treated as a bone cyst; amputation was done later, but the patient died of metastasis.

DISCUSSION

Dr. Rudolph Matas, New Orleans: In one case in which, after removal of a giant-cell sarcoma from the humerus, there was a large cavity, I used about an ounce and a half of Mosetig cement, and the patient later developed extreme symptoms of iodoform poisoning from which he recovered in 10 days and the arm healed with a perfect contour of the bone. I believe that in the bismuth paste we have a most valuable means of filling up cavities.

Dr. William L. Rodman, Philadelphia: I recall a case operated on in 1889 for large giant-cell sarcoma of the lower jaw by free chiseling and curettement, but without removal of the maxilla. The patient lived for more than ten years after this operation, and may be alive to-day.

Dr. Joseph A. Blake, New York: I had a case of sarcoma of the fourth finger. A simple operation in this case proved most satisfactory, and now, three years since operation, there is a normal phalanx.

Dr. Harry M. Sherman, San Francisco: In my experience salt solution poured into these cavities a little in excess just before the last stitches are taken is as good as any other material for filling. It is replaced by blood and obviates the necessity of putting in any foreign body.

Dr. Dudley P. Allen, Cleveland: Some years ago I removed the lower jaw of a patient for giant-cell sarcoma, leaving but a small portion of the substance of the jaw. I used a splint to hold the teeth in place. The patient recovered entirely and is now well.

Dr. William S. Halsted, Baltimore: In a case of myxoma of the humerus, although the disease involved the bone from one end to the other, there was no cyst and no fibrous tissue. The bone was excised four years ago excepting for a strip posteriorly and at the lower end, and the entire cavity carefully swabbed out with phenol. The patient made a good recovery and had a strong humerus, but there were implantation recurrences in the soft parts on two occasions. The patient is now perfectly well.

Dr. Nathan Jacobson, Syracuse: I recall a case of giant-cell sarcoma of the jaw in which I did a partial excision of the upper jaw for giant-cell sarcoma about 25 years ago. The patient is still living. There was never any recurrence. In my experience in those cases of giant-cell sarcoma where there is reasonable cleaning out there is seldom a recurrence of the growth.

Dr. A. Von Eiselsberg, Vienna: In such cases as these we are in the habit, before finishing the operation, of pouring boiling water into the wound in order to destroy all the germs, and have found it a most satisfactory method.

Diagnosis and Surgical Treatment of Esophageal Diverticula

Dr. Charles H. Mayo, Rochester, Minn.: Most cases of esophageal diverticula are pharyngo-esophageal. The condition is confined to adults. Dysphagia is the most common symptom; cough and dyspnea are common. Distended sacs are often visible in the neck and can be emptied by pressure. The condition is disclosed by probing and by radiograph of the bismuth-distended sac. H. S. Plummer's method of diagnosis is a combination of the technic of Mixter and Dunham, as used in stricture. The patient swallows a silk thread which passes into the intestine. The Plummer perforated acorn probe passed on the thread gives the depth of the pocket and location of its neck. Gastrostomy for temporary feeding may be necessary. Operation is by lateral oblique incision; blunt dissection; exposure of sac and excision; closure by suture; rubber tissue drain. There have been 8 patients in the Rochester clinic; 6 operated on successfully and 2 not operated on.

DISCUSSION

Dr. Samuel J. Mixter, Boston: I have operated in 3 cases of esophageal diverticula. When operation is not done, by the passage of very large bougies or probangs by means of a string guide a sufficient dilatation of the spur can be caused to allow the passage of food sufficient to keep the patient alive. I have about half a dozen such cases now.

Dr. George W. Crile, Cleveland: I wish to record two cases of operation for esophageal diverticula, in both of which recovery resulted.

Dr. John B. Murphy, Chicago: The enucleation of the sacs of diverticula is not a difficult matter in itself, but it leaves a large cavity, and it is difficult to avoid the danger occurring from leakage at the suture, infection from the mouth, and particularly the action of the salivary glands on the loose connective tissue of the mediastinum. I believe not opening the sac at all is the only safe procedure.

Dr. George E. Brewer, New York: The presence frequently during the day of an accumulation of thick, tenacious mucus which the patient will regurgitate to get relief is a characteristic symptom of esophageal diverticula. My own experience has been limited to 3 cases and one operation, on a woman, 80 years of age, who had lost 50 pounds through starvation. She made a perfectly good recovery from the operation.

Dr. Albert Vander Veer, Albany: I would refer to two cases of esophageal diverticula, one in a physician who refused to have an instrument passed and who subsequently died of an acute pneumonia; the other occurring in a woman, about 50 years of age, in whom it was impossible to get into the stomach with any form of instrument, and I therefore did a gastrostomy. The patient made a splendid recovery. She now alternates between tube feeding and the natural method.

Some Observations Regarding Thoracic Surgery on Human Beings

Dr. Willy Meyer, New York: I have operated in 10 cases with the help of my differential pressure apparatus for affections of the pleura, lung and esophagus. In the case of two young patients, 6 and 11 years old respectively, who had suffered for years from bronchiectatic abscess symptoms, and were bad risks, I extirpated a lobe of the lung in each case, but neither recovered. Three times exploratory thoracotomy was done for cancer of the esophagus with recovery. In order to do good surgical work when operating for a malignant stricture of the esophagus, I have found it necessary to get the scapula out of the way and, therefore, propose as a preliminary operation the Schede-Friedrich flap operation, by which the entire shoulder girdle is turned up, thus permitting the surgeon to make his incision into the thoracic cavity wherever required; often two incisions are necessary.

The only hope of operative success in cases of esophagus cancer lies in early operation, certainly before the intimately adjacent pneumogastric branches are involved, and the first step of such operation should be to free these nerves. Their involvement will more or less decide the operability or inoperability of the given cases. Up to the present time resection of the esophagus has a mortality of 100 per cent.

End-to-End Intestinal Anastomosis by the Invagination Method

Dr. C. L. Gibson, New York: End-to-end intestinal anastomosis by telescoping one segment into the other has been practiced from time immemorial, but at present has no recognized position in surgery. As a result of animal experiments and five successful cases I believe that with my present technic it furnishes a method for which there is a demand, particularly in the surgery of the lower end of the colon. The technic is as follows: The upper cut edge of the gut is seized with two Kocher clamps and introduced into the lumen of the lower end and maintained there by an assistant. The extent to which it is feasible to accomplish this invagination will vary. The gut is rotated about a quarter circle so that the non-peritoneal covered surfaces do not entirely approximate in the circumference. Eight to twelve interrupted silk sutures are introduced thus. A Lambert suture is begun on the lower segment, the needle issuing just short of the cut edge, on the upper segment the needle is introduced just above the line where the cut edge of the lower segment lies against the intact wall of the upper. When the knot is tied the free cut edge has been turned inward, and only the peritoneal surfaces are in contact. A continuous running suture is applied over this area further invaginating the first ones, the Kocher clamps being previously withdrawn.

Dr. Charles H. Mayo, Rochester, Minn.: The invagination method is a good one in the removal of tumors low in the sigmoid, at the upper rectum; in fact, it is about the only way you can get a union, to invaginate the upper end into the lower.

Abnormal Position of the Duodenum

Dr. G. E. Armstrong, Montreal: In the anomaly reported the duodenum ran to the right and then turned downward external to the hepatic flexure, ascending colon and cecum, and, merging into the jejunum, passed from without inward below the cecum into the small intestine area. The duodenum was completely surrounded by peritoneum. It had a long mesentery throughout and could easily be held two or three inches in front of the abdominal wall. The head of the pancreas, closely applied to the duodenum, was visible and palpable between the layers of the duodenal mesentery, and readily followed the duodenum when the latter was brought outside the body. There was no ligament of Treitz and no fossa duodeno-jejunalis. The condition is clearly one of arrested development. The cecum in this case did not mount upwards to the lower hypochondrium and did not pass in front of the loop of the duodenum. The cecum did not descend to its usual final resting place in the right iliac fossa. It was high, completely surrounded by peritoneum, very movable, and could be brought out through the epigastric incision and held eight inches in front of the body.

DISCUSSION

Dr. Maurice H. Richardson, Boston: I have observed a case in which the appendix, the gall-bladder, the liver and the ileocecal valve were on the left side, the spleen on the right side, and the heart on the right side.

Dr. Emmet Rixford, San Francisco: I would put on record a case of failure of rotation of the primary intestine.

Dr. Leonard Freeman, Denver: I had a case in which acute dilatation of the stomach followed an unimportant pelvic operation, and which at autopsy showed the duodenum passing directly beneath the liver and firmly attached to the posterior abdominal wall and around the right side as far as the hepatic flexure of the colon.

Dr. Joseph A. Blake, New York: I have met with two cases of abdominal position of the duodenum.

Dr. Alexander Primrose, Toronto: I would emphasize the fact that these conditions of abnormality in the position of the duodenum may occur without giving rise to the slightest symptoms.

Dr. Joseph C. Bloodgood, Baltimore: I would record one other anomaly of the intestinal tract which I think must be very unusual, namely, absence of the appendix.

Medicolegal

Violation of Medical Practice Act by "Doctor of Vital Science"

The Supreme Court of Iowa says, in State vs. Adkins (124 N. W. R. 627), that, prior to having attained his majority, the accused had led a bucolic life, and thereupon entered a "college of psychic-sarcology" in Missouri. Three years were devoted to the study of psychology, neurology, hygiene, dietetics, biology, anatomy, diagnosis, and actual practice. Having passed an examination on all branches appertaining to the science of "vital healing" he was granted a "diploma," and the degree of "doctor of vital science" conferred on him. Equipped with "all the rights and privileges pertaining to said degree," he returned to his father's house with the benevolent design of curing "all diseases without drugs, medicines, or surgical operations."

Quite naturally he first directed his attention to the appendix, insisting that "no part of the body is useless, but it takes all and every part to make up the perfect machine." In the local newspaper he wrote eloquently of the wrongs perpetrated by modern surgery, and directed attention to his "own peculiar methods" of healing by "natural laws." "When people learn," he said, "what appendicitis really is, they will understand that the removal of the vermiform appendix by a surgical operation is a crime against Nature. Then surgical operations will be abandoned and rank thereafter as a cruel and barbarous practice—the outgrowth of ignorance and stupidity. . . . Appendicitis as well as most every kind of disease yields very readily to the vital science treatment, which . . . is applied by Dr. L. M. Adkins' own peculiar methods and there are evidences of remarkable cures. For testimonials and other information call on or address Dr. Adkins," etc.

Later on, in sympathetic exaggeration, he again undertook to turn people from the surgeon's knife to "vital science institute . . . where all manner of diseases are treated successfully. . . . Surgical operations to remove the appendix have been a costly experiment to humanity. Not only has the sufferer been subject to the torture of the surgeon's knife, from which many never recover, but, should life be continued, a recent discovery of medical experts shows that eighty per cent. of those who survive the operation for appendicitis afterwards go hopelessly insane. This hitherto unthoughtof calamity will bring sorrow and regret to the homes of thousands of the survivors of this terrible operation. While people are suffering and dying with appendicitis, the news is being carried to all parts of the country of the new method known as vital science, which cures appendicitis in almost every case. This method of treatment uses neither drugs nor surgical operations, but is in perfect harmony with Nature's laws. There is a place in this city where the vital science treatment is given, known as the vital science institute, where all manner of diseases are treated successfully. For further information call on or write Dr. L. M. Adkins," etc.

He testified that he had treated several patients, and thus described his method: "Our system of treatment is by manipulation, stimulating the nerve centers so as to increase their vital force, the action of the blood and also the action of the muscles and all of the organs of the body, stimulating them up to their normal action by physical contact."

Enough has been said to indicate that the young man, even though a genius in the healing art, both publicly professed and undertook to heal and cure the afflicted, and, as this was without first having procured a license from the state board of medical examiners, he was rightly convicted of practicing without a license; and the judgment is affirmed.

Essential to Charge of Unlawfully Issuing Prescription for Liquors

The Kansas City Court of Appeals says that the case of State vs. Hume (124 S. W. R. 1099) was begun by an information charging the defendant, a physician, with unlawfully issuing a prescription for intoxicating liquors, in violation of Section 3050 of the Revised Statutes of Missouri of 1899, but that the conviction was not warranted. No offense was charged in the information. The innocence of the defendant should have been negatived. The charge was so framed that while it charged the intoxicating liquor was to be used as a beverage, and not a medicine, by the man who obtained the prescription, it did not connect the defendant with a knowledge of that fact, or with a purpose or intent of its being so used. If an indictment should charge that a physician issued a prescription to a person for intoxicating liquor "to be used" as a beverage, it might very well be said, thus closely connected, that that was charging that the physician issued it for the purpose of its being used to get the liquor as a beverage. But here the matter of the charge of issuing the prescription was so disconnected from the use to which the liquor was to be put by the party obtaining it that, while the latter was well charged with the unlawful and guilty knowledge and intent, the physician was not included with him. As was said in another case, on the same subject, a distinction is observed and must be taken by the court in administering the statute's provisions, between the contemplated use of the prescription and the contemplated use of the liquor after it is procured.

Ancestral and Personal Disabilities No Defense to Crime

The Court of Appeals of New York says, in the homicide case of People vs. Coleman (91 N. E. R. 368), that certain affidavits, briefly summarized, indicated that the defendant had been a backward, sickly child, somewhat weak-minded and morose, given to occasional periods of religious exaltation, suffering much from indigestion and headaches, and predisposed to pulmonary troubles; that his father was a dyspeptic; that there was tuberculosis in his mother's family; that his sister died of that disease; that his great-grandmother was insane; that a paternal aunt had violent hallucinations; and that an uncle was a religious fanatic. But all these things might be true without connecting the defendant with any taint of insanity or defect of reason that rendered him legally irresponsible for his acts. Few human beings are physically or mentally perfect. A large percentage of the human race are the victims rather than the beneficiaries of their heredity. If there were no physical and mental defectives, there would probably be no crime. Such a family history as was ascribed to the defendant is not uncommon in criminal annals. There was an utter absence of evidence tending to show with reasonable certainty that the defendant at the time he killed his wife labored under any defect of reason which rendered him incapable of knowing the nature and quality of his act or of knowing that it was wrong. Measured by that legal test, the evidence submitted on the motion for a new trial was insufficient and the application was properly denied.

Waiver of Privilege as to One Physician a Waiver as to All

The Kansas City Court of Appeals says, in the personal injury case of O'Brien vs. Western Implement Manufacturing Co. (125 S. W. R., 804), that the plaintiff had two physicians attending his injuries, one of whom he introduced as a witness, who testified as to such injuries. The defendant called the other physician, and offered to prove by him the condition of the plaintiff's injuries at the time. On objection by the plaintiff, the witness was excused on the ground of his incompetency. This was error. Having introduced one of his physicians to prove the condition of his injuries, the plaintiff waived the privilege of the statute. It is universally held that this, being a personal privilege, may be waived. In Elliott vs. Kansas City, 198 Mo., 593, the court in passing on the question held that, where the privilege of the statute had once been waived, the waiver could not be withdrawn. The plaintiff's assumption was that, notwithstanding the privilege was withdrawn by the introduction of one of his physicians, it was not waived as to the other. His position was not tenable. In the above case the court quotes with approval the holding in Morris vs. Railroad, 148 N. Y., 92. It is there said: "When a waiver is once made, it is general, and not special, and its effect cannot properly be limited to a particular purpose or a particular person. After the information has once been made public, no further injury can be inflicted on the rights and interests of the patient, as the statute was intended to protect, by its repetition at another time or by another person."

8 *Pharmacopeia Revision from the Standpoint of the Medical Teacher of Drugs. W. A. Bastedo, New York.
9 Physicians in Fiction. C. D. Spivak, Denver.

8. **Pharmacopeia Revision.**—From the point of view of the medical teachers of drugs, according to Bastedo, a large and comprehensive pharmacopeia is not of necessity a disadvantage, and, by allowing for diversity of opinion, may be an advantage. Medical teachers have a deep interest in the formulation of principles to govern the selection and standardization of preparations and their doses. For the revision, Bastedo suggests as desirable for teaching purposes the omission of confusing duplicates, and of crude commercial substances for internal use whose preparations are made of some different form of the drug; the simplification of mixed remedies; the standardization of doses of potent preparations strictly in accordance with the amount of drug represented; and, where practicable, uniform percentage strengths for all potent preparations of a given class. Further, the teachers would desire the addition of the genitive ending of the Latin name of each drug and the accusative ending for names of prepared objects, such as compound cathartic pills; also with each drug a list of its pharmacopeial preparations with their strengths.

It will be agreed, he says, that, for medical teaching, which must of necessity be in advance of the practice of the main body of the profession, the selection of drugs should be based on reliable pharmacologic and clinical data regardless of the extent of their use. But for a working formulary and book of standards, such as the pharmacopeia, the selection should be based on the extent of use as indicated by the prescriptions of practitioners in all parts of the country. The dropping from use of the inferior substances will depend largely on the establishment of more uniform and more scientific teaching.

22 Dextrocardia. G. [illegible] Weinsberg, St. Louis.

11. **Perineural Injections for Trifacial Neuralgia and Sciatica.**—Hecht has treated 60 cases of trifacial neuralgia by deep injections of alcohol, 70 to 90 per cent with success. A total of 180 injections was given, an average of 3¼ injections, to subdue pain. Thirty-seven patients were distinctly benefited; eleven were improved; eight unimproved; four were aggravated. One patient was free from pain for a year and eight months; the shortest interval of freedom from pain was 2 weeks; several were free from pain for a year. If reinjected, pain was again subdued.

13. **Rhizomelic Spondylosis.**—Williams gives the histories of three cases of rhizomelic spondylosis in which there were great weakness of the muscles of both legs, with permanent unilateral toe-drop, sensory changes resembling those found in syringomyelia, and an unusual form of vertebral exostosis. A fact of importance is intermittence of the joint affections, they becoming almost well at times, and later being again involved.

15. **Typhoid Fever.**—Claytor pleads for a more liberal diet in typhoid. His patients are far more comfortable, not having that ravenous hunger that patients have when fed entirely on liquids, are not so profoundly nervous, and are better nourished. Neither hemorrhage nor perforation is more frequent than among those kept on liquids, and delirium is less pronounced. Convalescence is more rapid, and the patients return to a good general condition and a normal physical and mental state far more rapidly. The diet should be such as to keep up the body equilibrium as much as possible; it should be easily digestible, innocuous and palatable. Claytor allows soft-boiled eggs, scraped meat, rice, scraped apple, custard, etc.

17. **Function of the Corpus Luteum.**—The principal features in the sexual cycle Loeb believes to be as follows: At a certain period the animal enters the period of heat; a few ovarian follicles rupture and become transformed into corpora lutea. In the early stages of their life, the corpora lutea constitute one of the factors initiating growth processes in the uterine mucosa by means of an internal secretion. If no pregnancy takes place, these proliferative phenomena are slight. If pregnancy does take place, the ovum adds a mechanical stimulus to the sensitizing action of the corpus luteum and a maternal placenta is produced. The ovum can be substituted by an indifferent foreign body. Within a few days this receptive period of the uterine mucosa is followed by a refractory period, in which the uterus no longer reacts to mechanical stimuli, notwithstanding the functionating of the corpus luteum. In this period the corpus luteum exerts a new function, it prevents the rupture of new follicles and prolongs artificially the period of the sexual cycle. During pregnancy some factor extends the life of the corpus luteum, and the period of the nonrupture of follicles is thus prolonged. At the end of the pregnancy, the corpus luteum degenerates, new follicles rupture, and a new cycle begins; the pregnancy as such does not, however, prevent a new rupture of follicles. If no pregnancy is present the factor that prolongs the life of the corpus luteum is absent. The corpus luteum degenerates much earlier and permits new follicles to rupture. The changes in the corpus luteum and in the uterus are accompanied by rhythmic changes in the ovarian follicles. The conception of this mechanism is not hypothetical, but rests on a secure foundation of experimentally established facts.

19. **Amebiasis.**—Of the 42 patients seen by Allen since April, 1908, 12 died, a fatality of 28 per cent.; 16 of the 42 gave no history of frequency of the bowel movements; 10 out of 16 had bald tongue, which Allen believes to be indistinguishable from that of pellagra. Of 25 cases in which the hemoglobin was estimated, in 6 it was about 80 per cent., and in 19 below 80 per cent.; in 1 the hemoglobin was below 10 per cent. In making a routine blood examination the presence of a moderate eosinophilia has repeatedly directed Allen's attention to the intestinal tract, with the result that amebas were found in the stools. Out of 29 cases in which differential counts were made, 14 showed eosinophilia of 5 per cent. or over, 2 between 4 per cent. and 5 per cent., and 11 below 4 per cent.; one case complicated by *Ascaris lumbricoides* showed 17 per cent.,

and one complicated by hookworms showed 5.2 per cent. In 1 case of combined amebiasis and ankylostomiasis the removal of the hook worms caused the eosinophilia to drop from 10 per cent. to 5 per cent. in 8 months. This leads Allen to believe that a moderate increase in the eosinophils will be found in over 50 per cent. of patients, if not less than 500 white cells be counted.

Since amebas can be grown in alkaline bouillon, the reaction of amebic stools may prove of interest. In 14 cases in which this point was noted, litmus paper showed 10 alkaline, 2 neutral and 2 acid; unfortunately, these acid stools were not tested with phenolphthalein. In this connection it is interesting to note that out of 35 cases *Trichomonas vaginalis* was present in 19 patients. In three patients a diagnosis of abscess of the liver was made; two of these left the hospital within 24 hours and were lost sight of; the third patient showed abscess at autopsy.

Although all known methods of treatment were tried by Allen, he is confident that not a single permanent cure has been effected. Hence, he concludes that treatment has been radically defective, or that the medical treatment of amebiasis is only palliative, and can hold out no hope of a permanent cure.

26 *The Effect of Tobacco on the Ear and Upper Respiratory Tract. H. O. Reik, Baltimore.

23. **Dyspepsia and Indigestion.**—Munro urges the general practitioner to consider the probability of some simple surgical lesion of the abdominal viscera in his cases of persistent recurrent indigestion; that where such a lesion does exist, surgery is the safest and surest means at our disposal to bring about a permanent cure; that his neurotics with indigestion secondary to surgical lesions have the right of relief from their local trouble; that, finally, there is a type of dyspepsia most naturally ascribed to gastroduodenal ulcer, but which is really secondary to an appendicitis and which is curable to a degree not yet definitely determined by a simple appendectomy.

26. **Effect of Tobacco on Ear and Upper Respiratory Tract.**—From such facts as Reik has been able to collect it does not appear, at least it has not been proved, that tobacco causes any definite characteristic lesions of the nose, throat or ear. While it is possible that the excessive use of tobacco may, by indirect action, produce a toxic effect on the olfactory and auditory nerves, with resulting impairment of the sense of smell or of hearing, there is not at the present time any definite laboratory proof for such an opinion, nor is there sufficient clinical evidence to substantiate the belief. The ill-effects of tobacco smoke on existing diseases of the throat, arising from other causes, is established and is the same as would be observed from any other form of irritation.

That gastric and systemic disturbances may arise from excessive use of tobacco, in any of its forms, is unquestioned; the nicotin content of tobacco is a recognized poisonous substance and, in the process of smoking, there are evolved other injurious chemical products. Carbon monoxid is probably a more dangerous and injurious constituent of tobacco smoke than is nicotin, only a very fractional amount of which ever enters the tissues. If there is any more danger to be anticipated from cigarette than from cigar smoking it is to be looked for solely in the inhalation of the smoke; cigarette smoking without inhaling is no more injurious than is pipe or cigar smoking. probably not so much so, unless enormous numbers be smoked.

30. **Tetanus.**—Wilcox emphasizes the importance of regarding a certain class of wounds with suspicion, and the results to be obtained from large, repeated, prophylactic injections of antitetanic serum and the value of intraspinal injections of magnesium sulphate to control the spasms, thereby assisting Nature in eliminating the toxins which have become fixed in the nervous tissues. He holds that the intraneural injection of antitetanic serum deserves a thorough trial in conjunction with the above.

38. **Inflammation.**—Inflammation, says Opie, is a process which tends to render harmless an injurious substance; it has its site in the interstitial tissue of the body. This tissue consists of fixed cells and fibrillated substances and is penetrated by closed lymphatic vessels. With inflammation certain cells migrate through the wall of the blood-vessels of the part and enter the spaces within the interstitial tissue. Some of these cells are destroyed; others penetrate the endothelial membrane which forms the lymphatic capillaries and hence are carried by way of lymphatic vessels to the regional lymphatic nodes.

Bacteria and many other injurious substances are attacked and ingested by polynuclear leucocytes. These leucocytes are, in turn, ingested by large mononuclear cells (macrophages) which quickly appear at the site of inflammation. The origin of these mononuclear cells is still undetermined. Ingestion of polynuclear leucocytes and other cellular material is begun at the site of inflammation and completed in the regional lymphatic nodes.

The ability of phagocytic cells to remove injurious material is dependent on the possession of proteolytic enzymes. Peculiar to the polynuclear leucocytes is an enzyme which, like trypsin, exerts its digestive action in an alkaline medium. The serum of the blood contains an antienzyme which restrains the action of this enzyme should it be set free by disintegration of the leucocytes; the action of the enzyme is thus limited to the locality in which it accomplishes its proper function, namely, within the cell. When enzyme is set free in such quantity that it overbalances the antienzyme of the exuded serum, suppuration occurs, for the purulent exudate has in virtue of its unrestrained enzyme acquired the power to soften and erode the adjacent tissues.

The mononuclear phagocytes which appear in the late stages of acute inflammation, the similar cells which appear in the regional lymph-nodes, and the cells of similar structure which constitute the greater part of tuberculous tissue contain an enzyme which, like pepsin, digests in the presence of acid. Such phagocytes are active at the site of inflammation, but their work is completed in the regional lymphatic nodes. Inflammation is the process by means of which cells and serum accumulate about an injurious substance and tend to remove or destroy it. This process does not include the regenerative changes which replace injured tissue by newly formed parenchymatous elements or by new interstitial tissue.

39. **Hemoglobin of Colored Laborers in Panama.**—Brem and Zeiler found that the average hemoglobin of healthy colored men of the tropics is about 83 to 85 per cent. The average hemoglobin of Barbadian and Jamaican laborers was 72.7 and 73.7 per cent., respectively; that of Martiniquans 55.2 per cent. Of 277 patients, 234, or 84.5 per cent., had malarial fever; 15.5 per cent. had pneumonia, typhoid, dysentery, liver abscess, tuberculosis, nephritis, etc. Uncinariasis was found in 36.1 per cent.; amebiasis in 24.5 per cent. The hemoglobin curve of malarial patients varies inversely with the number of previous attacks of malarial fever until a relative immunity or tolerance for the malarial poison is developed, when a rise of hemoglobin occurs. This rise does not take place in patients infected with uncinaria. Uncinariasis complicating malaria in colored men causes a reduction of hemoglobin, which averages 6 per cent. less than that of uncomplicated malarial infections. The complication causes more than double the proportion of anemic cases. Amebiasis without dysentery does not appreciably affect the hemoglobin curve. Conditions of life on the Isthmus of Panama do not in themselves affect the hemoglobin of colored laborers. Blood destruction is a question of infection only.

40. **Paroxysmal Hemoglobinuria.**—In the case presented by Neilson and Terry any severe chilling of the patient's skin caused a temporary hemoglobinuria, drowsiness, regurgitation of food and other minor symptoms to be mentioned later. The phenomena were produced either by a chilling of the general body surface or, what was more common, by the mere exposure of the hands and face to cold, damp winds, or by the wetting of the feet in cold weather. The phenomena were produced experimentally in the laboratory by dipping the patient's feet in water reduced to a temperature of 9 to 12 C., even when the general room temperature was 27 C. The object of the experiments was to determine the inhibitory effect of calcium chlorid on the hemolysis of red blood corpuscles by the patient's serum. While the authors do not state definitely that calcium chlorid when administered by the mouth does prevent this hemoglobinuria by foot-baths, they claim that in view of the inhibitory effect on hemolysis in the test tube they feel justified in concluding that if sufficient calcium chlorid could be introduced into the blood, and retained, no hemoglobinuria would occur.

41. **Adams-Stokes Syndrome.**—A careful study of a patient for 5 years and subsequent examination of the tissues concerned, convinced Krumbhaar that Adams-Stokes' syndrome and complete heart-block can exist uninterruptedly for years with little or no lesion of the bundle of His. Whether in such cases there is a structural lesion or whether the difficulty is purely functional, has not yet been determined; but it is probable, says Krumbhaar, that there may in some cases be two or more contributing causes, both functional and organic. A possible explanation of the dissociation of auricle and ventricle in the present case may be that following a fibrosis of the sinoauricular bundle of Keith, the two chambers beat with independent rhythm rather than that the impulse was not properly conducted to the ventricle.

42. **Bone Metabolism and Osteomalacia.**—The treatment of osteomalacia, according to McCrudden, depends on the individual case. He regards it as probably useless to resort to castration in a condition of non-puerperal osteomalacia or a very severe case of puerperal osteomalacia, and, in mild cases of puerperal osteomalacia, it is usually needless to resort to this operation. Good hygienic conditions should be relied on to improve a mild case and the patient should be advised concerning the dangers of rapidly occurring pregnancies. The recent results in bringing about artificial menopause by the x-rays leads him to suggest that this treatment might be tried instead of the more severe operation in a case in which sterilization seemed advisable.

43. **Herpes Zoster of the Cephalic Extremity.**—Hunt believes that we are justified in isolating a large and varied group of cases, characterized by herpes zoster of the cephalic extremity associated with facial palsy, auditory, glossopharyngeal and pneumogastric symptoms, and in regarding them as constituting a well-defined clinical picture. A number of syndromes are thus united in a symptom-complex, having a common etiology and pathology. He is convinced that cases belonging to this group are of much more frequent occurrence than might be inferred from the study of the literature. The reasons for which are to be found in the smallness and inaccessibility of the eruptive areas, making their detection difficult; or all traces of the eruption may have disappeared before the case comes under observation, when a retrospective diagnosis might be difficult or impossible.

It also seems probable, that some cases which are interpreted as rheumatic palsies of the face, palate and even the larynx, may belong to this group; as well as toxic unilateral palsies of obscure origin.

51 Syphilis. J. Grindon, St. Louis.

50. **Meralgia Paresthetica.**—For about the last ten years of Sherwell's life, in the outer and lower two-thirds of his left thigh, after strenuous and long-continued exertion, as walking, riding and cycling, there has occurred in the region supplied by the external femoral cutaneous nerve, symptoms which he describes as follows: This region becomes the seat of a variety of perverted sensations, such as tingling, tenseness, or still more acute superficial tearing and darting pain, with numbing of sensation from the femoral exit of the nerve to a point just above the patella; this may be only a dull ache, but is usually more acute. It may begin as a glowing sensation also; the rest of the limb with its cutaneous envelope appears to be entirely normal; these symptoms soon subside on resting—sitting, or, better, lying down, but can be brought on readily by resumption of exertion. The painful sensations are like nothing so much as those of zoster, and it is Sherwell's belief that they are caused by the same mechanical means, viz., pressure on the nerve in its continuity, though probably not from the exudation pressure which occurs in zoster.

Sherwell is a healthy man over 60; so far as he knows he is physically sound and takes pleasure in protracted, and it may well be, extreme exercise of all kinds; the affection seems to be diminishing in intensity; for the last two years it has certainly not been so acute or prolonged. Sherwell has not changed his habits of exercise in the least. He frequently walks 5 miles, or even nearly double that distance, rather than use cars.

His conclusions as to the etiology of this condition are, in brief, these: that the condition comes from a constriction, or pinching, as it were, of the nerve as it passes through the tough fasciæ of a muscular individual; that that and the consequent irritation resulting therefrom, and possibly a transient exudation at the site of the constriction as well, between the sheath and nerve substance proper, causes all the symptoms; a temporary non-essential zoster as it were. The only aiding cause on which he lays any weight is a rheumatic tendency; a condition that may aggravate, as can be rationally concluded. Rest and perhaps slight massage produces rapid, though unfortunately, only temporary relief—not a cure.

63. **Carcinoma of the Penis.**—Of the 13 cases reported by Leighton, 7 came to operation; 1 patient was treated by simple amputation; another by amputation at the pubes with removal of the inguinal glands. The remaining five cases were so badly involved that no choice was left to the operator and a complete extirpation of the genitals with a dissection of the groin was made. Of these, one patient, far advanced, died on the fourth day from a pneumonia; another recovered and left the hospital, but a few weeks later suddenly dropped dead; autopsy by the coroner revealed no cause for the death. Another patient operated on four years ago is well and free from symptoms. The remaining two patients are well two years and one year, respectively, after operation.

93. **Importance of Parasitology.**—The subject of parasitology is one of great importance to medicine. A scientific knowledge of the structure, life history and habits of the parasites is of much value to the practitioner. Allen says that they consider this subject of such importance in Wisconsin that they are now giving at the university a course in medical zoölogy which deals primarily with the structure, reproduction and life history of parasites infesting man. It also deals with disease carriers, such as mosquitoes, flies and rats, and finally with venomous insects and reptiles.

101. **Removal of Gauze Sponge from Abdominal Cavity.**—The patient whose case is reported by Robb, complained of dysmenorrhea, menorrhagia and dragging pains in the lower abdomen, with frequent and burning micturition. On bimanual examination an adherent uterus could be made out posteriorly in the pelvis. Both Fallopian tubes and ovaries were enlarged and adherent. An abdominal section was performed. The adherent tubes and ovaries were removed after separation of a considerable number of intestinal and omental adhesions. Both tubes contained pus. During removal of the right tube and ovary the tube ruptured, allowing several drams of a purulent fluid to escape into the pelvic cavity. The pus was caught on a sponge and a couple of narrow gauze sponges were packed about the seat of the ruptured tube. The abdominal cavity was closed without drainage. There was a slight elevation of temperature for two days following the operation. Aside from this, however, the convalescence was uninterrupted. Twenty days after the section the cervix and perineum were repaired. Six weeks after the laparotomy the patient was discharged feeling well in every way.

In February, 1909, a little more than nine months from the time of operation, she was again admitted to the hospital complaining of some distress in the left lower quadrant of the abdomen. On bimanual examination a fluctuant movable mass, about the size of a closed fist, could be made out. Three days later the abdominal cavity was reopened through the line of the previous operation. The mass was found beneath the brim of the pelvis lying to the left of the median line, enveloped in a connective-tissue-like sac, and surrounded by the sigmoid flexure, the omentum, and several coils of the small intestines. During an attempt to separate the intestines from the mass the sac ruptured and a small quantity of purulent looking fluid escaped. At the mouth of the opening in the sac there appeared a whitish substance which proved to be a gauze sponge in a perfect state of preservation.

134. **A Traumatic Cataract Operation.**—This case proved to be a traumatic extraction of a cataract in capsule, followed by results comparable to those of the Major Smith operation. At the age of 24, the patient received an injury to his right eye from a piece of steel which reduced its vision to 6/200, his left eye, however, remained normal. Three years ago, at the age of 67, while laboring on his farm, he stooped to clean his plow and bumped his left eye against a projecting iron bar. He immediately covered the wounded eye with his handkerchief and sought relief, arriving at Windle's office within half an hour after the accident. On separating the eyelids in the process of examination, a large fragment of the lens was found lodged in the cul-de-sac. A slightly irregular linear wound was observed in the upper, outer portion of the cornea near the limbus, about 8 mm. in length. No lens débris could be discovered remaining in the eye. The corneal chamber was not entirely collapsed. A large fragment of the upper, outer portion of the iris had been torn away, forming a large coloboma; no incarceration of the iris, however, had occurred. Examination by the ophthalmoscope later on revealed clear media, excepting a small fragment of lens-capsule remaining at its lower attachment. Windle claims that this case of traumatic expression of the lens in capsule is a silent yet forcible argument in favor of the Major Smith operation.

7 *Interesting Case of Triplets. G. Aldridge.

7. **Interesting Case of Triplets.**—On examining a primipara aged 28, Aldridge found presenting outside the vulva the foot and leg of a fetus. This he was able to deliver quickly and easily, and found it to be a male mummified fetus of about 6 months' development. On further examination he felt a bag of membranes bulging at the os uteri and the head of a child presenting. The os being fully dilated, Aldridge ruptured the membranes and in about an hour delivered the patient of a living female child of about 8½ months' development. He then placed his hand on the abdomen to express the placenta, and after waiting some time with no result he again examined

the patient. The uterus had contracted firmly, but he could feel through the os the foot of another fetus protruding. This was gripped by the contracted uterus, and the patient, although uneasy, was having no pain. After waiting an hour he examined again and found the os uteri dilating and the leg as well as the foot of a fetus presenting. Gentle traction seemed to bring on pains, and in about 20 minutes he had delivered the woman of another fetus (male, mummified) of about four months' development. The placentæ were removed with difficulty. The two male fetuses were attached to one placenta, while the living child had a separate one. This was apparently a case of two ova, one of them double.

13 The Mechanical Effects of a Massive Right-sided Pleural Effusion. A. C. Geddes.

12. **End-to-End Suturing of Arteries.**—The method of end-to-end suture of arteries described by Smith is an evolution of the method set forth in his recent book on blood-vessel surgery. The suture material used is silk, for a vessel as large as the human femoral artery, No. 0000; for one the size of the radial about half that thickness. In addition, some fine chromicized catgut, No. 1 or No. 2, according to the size of the vessel, is required. The silk is used from the reel, and it is essential to thread the needle from the convexity of its curve toward the concavity. The catgut should for convenience be in straight lengths, that is, never have been wound on a reel. Smith uses an apparatus for sterilizing silk or catgut by superheated alcohol vapor. The suture method is an adaptation of the quill suture, the quill being represented by the chromic gut. The desideratum is to bring two endothelial surfaces together, yet to have a suture that penetrates every coat of the vessel, but causes a minimum of bare suture material to impinge on the lumen. The method is described fully by the author.

18. **Tuberous Sclerosis.**—Tuberous sclerosis is a rare developmental disease, interesting pathologically, because of the peculiar association of a characteristic nodular sclerosis of the cerebral cortex, and tumors of the kidney, heart, skin and other tissues. The case Fowler and Dickson record was an infant, aged 1 year, who had apparently developed in a normal fashion. It was suddenly seized with convulsions, lasting for several hours. It was in a semicomatose condition, with slight convulsive movement of the face. Lumbar puncture showed that the cerebrospinal fluid contained 40 lymphocytes per cm. Otherwise the examination was negative. The child remained in an apathetic condition for three weeks without the supervention of any further symptoms, and the cells disappeared from the cerebrospinal fluid. She then developed an empyema, which proved fatal. During the whole of the child's illness her appearance was indicative of cerebral mischief, but the symptoms, though at first suggestive of tuberculous meningitis, were too indefinite to admit of any diagnosis being arrived at.

On post-mortem examination the brain showed numerous hard nodules, mostly in the cerebral cortex, the arrangement of the convolutions of which was not appreciably disturbed, nor was the pia arachnoid adherent over them. These nodules, a dozen or more on each hemisphere, and varying from the size of a pea to that of a small walnut, consisted of neuroglial overgrowth, with corresponding diminution of the nerve elements proper. The surviving nerve cells were increased in size and showed all stages of degeneration and disintegration. Numerous smaller nodules projected into the lateral ventricles. In the right auricular appendix of the heart there were two small nodules of rhadomyoma, the histologic appearances of which corresponded to the classical descriptions of this very rare tumor. No lesions of special importance, apart from empyema, were found in any of the other organs.

28 *Epilepsy in Some of Its Gynecologic Aspects. W. J. Rutherfurd.

28. **Epilepsy.**—When between 15 and 16 years of age, Rutherfurd's patient began to menstruate for the first time. For three or four years previous to this she had had a fit at fairly regular four-weekly intervals, without the occurrence at any of these times of any menstrual flow. She had never had fits of any sort before the age of about 12 years, but has had them with regularity ever since. These fits were preceded by a cry and were accompanied by loss of consciousness and biting of the tongue, but never to her knowledge had she lost control of the rectal or vesical sphincter. In such a fit she occasionally fell heavily and sustained injury. At present, unless when held in check by appropriate medicinal measures, the fit occurs with regularity every month about a week before the onset of the menstrual flow, and with the one fit the tendency exhausts itself and does not reassert its presence until a full lunar month has elapsed. For a year or two, however, she had a series of single intermenstrual fits occurring exactly midway between the two periods; this was only at the onset of menstrual life, and she has not exhibited the phenomenon since.

She has now had four children, and always during the amenorrhea of pregnancy and of lactation she has found herself free from the fits, which recurred again and presented all their usual phenomena on her weaning the child. Menstruation has always been regular and absolutely free from pain, and particular inquiry failed to reveal any story of pelvic pain or of blood-stained discharge occurring at the middle of an intermenstrual period at any time in her life. Rutherfurd holds that such cases as these teach us that our conception of what does and what does not constitute *Mittelschmerz* must undergo considerable modification. In this case there was no pain, and apparently no discharge at the mid-interval periods, but their place was taken over a considerable time by recurring explosions of nervous energy of the nature of true epilepsy. The sequence of events as evolved in subsequent years proclaimed the real dependence of such manifestations on the cyclical pelvic changes, and established their claim to be regarded as a form of *dysmenorrhea sine dolore* of the intermenstrual type.

29. **Treatment of Retroversion of the Uterus.**—Chevrier prefers the modified Doléris technic for ligamentopexy and gives ten illustrations of the method, especially of the way in which the finger wrapped in gauze stretches the lips of the incision in the peritoneum, permitting the round ligament to be drawn through and the loop sutured after what he calls median reinforcement.

32. **Stretching the Vagina in Advance of the Fetus with Breech Presentation.**—Sauvage stretches the vagina with the Champetier de Ribes bag to facilitate delivery. In 32 cases it enabled spontaneous delivery in all but four instances. When forceps are required, this preliminary dilatation aids materially; done cautiously it does not harm the mother, while the advantage for the child is beyond question. In primiparæ it generally promotes delivery and seems to reduce by 25 per cent. the mortality of the children while they are in a better condition, not having suffered from the traumatism of compression from the soft parts. *He advises it also for shoulder presentation in primiparæ, and in multiparæ if the child is large, and gives the details of 50 cases in which this vaginal prefetal dilatation was applied.*

49 Pyloric Spasm in Infants. (Quelques considérations sur le pylorospasme du nourrisson.) H. Dufour.

48. **Form of Scoliosis Aggravated by Exercise.**—Ombrédanne has noticed that when some of the vertebræ have become wedge-shaped so that scoliosis has developed, any attempt to bend the spine forward causes torsion. Scoliosis due merely to muscular insufficiency or deformity of the intervertebral discs, without deformity of the bone, corrects itself as the spine is bent forward, and gymnastic exercise is the most essential factor in treatment. But in scoliosis with wedge-shaped vertebræ, the deformity increases as the spine is bent forward; every such movement aggravates the lesions and deformity and should be strictly forbidden.

60 Advantages of Prolonged Anesthesia with Ethyl Chlorid: 75 Cases. M. Boureau.

56. ***Eclampsia and Morphin.**—Rouvier and Laffont state that* recovery was much more rapid and complete in their cases of eclampsia *in which they used morphin, injecting 0.01 gm. at a time, repeated from 3 to 5 times at 3 or 4 hour intervals,* supplemented by inhalation of chloroform and copious rinsing out of the stomach and intestine. They give the details of 2 cases, emphasizing the rapid subsidence of coma and the prompt recovery; with other measures the patients were several days recovering complete consciousness.

58. **Ptosis of the Cecum.**—Lardennois remarks that the disturbances from ptosis of the cecum have frequently been erroneously ascribed to wandering kidney, ovarian cysts, tubo-ovarian varicocele, displacement of the uterus, neuralgia or neuropathies, but once suspected the symptomatology is instructive. The pain, oppression and dragging down sensations are below McBurney's point, and the cecum may be felt as a soft, fluctuating tumor; it gives a relatively dull note on percussion during a painful attack, with gurgling sounds as the attack subsides. He adds that the pathognomonic sign is that when the contents of the ascending and transverse colon are pushed back toward the cecum, this causes pain in the right half of the pelvis, while the pain disappears if the contents of the prolapsed cecum are gently worked along from below upward, toward the colon. Dietetic measures, massage and exercise of the abdominal muscles are the main reliance in treatment for the milder forms, and he is convinced that many cases of supposed chronic appendicitis in which a cure was realized by massage and purgatives were in reality merely cases of ptosis of the cecum.

If in operating on an inflamed appendix the cecum is found much over 4 inches long, he advises fastening the cecum to correct any tendency to ptosis later. This should also be advised if the disturbances persist unmodified by medical measures and massage.

Revue de Chirurgie, Paris

May, XXX, No. 5, pp. 751-966

61 *Primary Sarcoma of the Articular Synovial Membranes. F. Lejars and H. Rubens-Duval.
62 *Fatality During Momburg Belt Constriction. (Mort subite au cours de l'hémostase par le procédé de Momburg.) G. Gross and A. Binet.

63 Traumatic Radicular Paralysis of the Brachial Plexus. Vandenbossche.
64 *Continuous Oxygen Irrigation of the Abdomen in Abdominal Surgery. (Emploi du courant continu d'oxygène en chirurgie abdominale.) T. Weiss and L. Sencert. Commenced in No. 4.
65 Operative Treatment of Cancer of the Testicle. M. Chevassu. Commenced in No. 4.

61. **Primary Sarcoma of the Articular Synovial Membranes.**—The lesion develops very insidiously, it is extremely indolent and does not interfere with the movements of the joint; from 2 to 13 years had elapsed before operative treatment in the 16 cases on record. The results of conservative operations are not encouraging and Lejars deems amputation at once the wiser course or, at least, if the lesion shows signs of recurrence after a primary conservative operation. In the personal case reported and in 13 others the knee was the seat of the growth; in the others the ankle. The patients were between 20 and 40 years old in nearly every case. A history of trauma affecting the joint is mentioned in several instances.

62. **Fatality from Momburg Belt Constriction.**—In the case reported the rubber tubing was wound around the waist to prevent hemorrhage during disarticulation of the hip for a tuberculous process in knee and hip joint which had much debilitated the patient, a woman of 27, during the last two years. No abnormal sounds were heard over the heart. The constriction was applied very gradually and the operation terminated without mishap. The tubing was then unwound and in about a minute the patient collapsed. Autopsy showed the right heart acutely distended. This was favored by unsuspected fatty degeneration of the heart muscle and old mitral and aortic endocarditis. The case teaches the importance of applying and removing the tubing very slowly and cautiously to avoid sudden changes in the condition of the circulation. Willems has reported a case in which blood issued from mouth and nose during the belt constriction; Guinard, a case of blood-stained sputum; Pieri of intestinal hemorrhage; Kempf of gangrene of the thigh, and de Bovis, a fatality possibly due to the constriction.

64. **Continuous Current of Oxygen in Local Treatment of Abdominal Disease.**—The first part of Weiss and Sencert's communication was summarized in The Journal May 28, page 1829. They here give the details of sixteen cases out of a much larger mass of material to show the advantages of continuous irrigation of the interior of the abdomen with a constant flow of oxygen. It has abundantly demonstrated its usefulness, they say, as an aid to drainage, checking or preventing absorption from the abdominal cavity, stimulating peristalsis, especially when combined with proctoclysis, and exerting in general a stimulating action on the cardiovascular apparatus. They urge that it should rank with proctoclysis and lavage of the stomach as a routine measure in prevention and treatment of peritonitis, etc.

79 Balneotherapy in Urinary Disease. Wasserthal.

70-71. **General Anesthesia by Intratracheal Insufflation.**—Unger and Bettmann have modified the Meltzer technic for respiration by intratracheal insufflation, the main feature of which is the use of a two-way tube carried down into the trachea to the bifurcation of the bronchi. This ensures constant evacuation of the used air (even without respiratory movements) which is the chief point of superiority of this over other technics for artificial respiration and for inducing differential pressure in the lungs in thoracic surgery. Instead of the apparatus devised by Elsberg for the purpose, they use an ordinary oxygen tank connected by a T-tube with a Wolff flask containing a little ether, the flow of the mixed ether and oxygen being controlled by a valve. Their experiments with it have been encouraging. Elsberg reports two clinical cases in which the method with his apparatus was successfully applied in operative treatment of an abscess in the lung or pleura.

80 *Liver Abscess During or Consecutive to Typhoid. (Ueber Leberabscesse im Verlaufe und Gefolge des Typhus abdominalis.) E. Melchior. Commenced in No. 5.

80. **Abscess in the Liver in the Course of or Consecutive to Typhoid.**—Melchior critically reviews 94 articles that have appeared on this subject and tabulates the details of 25 cases of solitary abscess in the liver of typhoid origin. The prognosis is unfavorable when the abscess develops from spread of a typhoid cholecystitis or thrombophlebitis. The clinical picture of typhoid appendicitis resembles that of typhoid perforation of the bowel. In 5 cases the typhoid appendicitis was responsible for development of a pylephlebitic liver abscess, all fatal. Appendicitis complicating typhoid should be treated as under other circumstances; after the abscess in the liver has developed it is too late for an operation, as likewise when the abscess is of pyemic origin. With a solitary abscess, prompt operative treatment with ample outlet for the pus is showing constantly better results as the technic is being perfected. In the 12 operative cases all but 2 of the patients recovered, while only 2 recovered out of 9 patients under medical measures alone. Pneumonia in the superior lobe was observed as a complication in one case and severe diarrhea in another, but both patients recovered. The clinical picture of typhoid solitary abscess in the liver opens with high fever and pain in the liver region about two weeks after defervescence in a mild or moderate typhoid, generally in a male patient. In some cases there is a chill; jaundice is still rarer. The liver visibly increases in size and is usually tender. Contrary to what is observed with a pleural effusion, the excursions of the lower margin of the lung are not restricted. Typhoid cholecystitis generally comes on during the febrile phase of the typhoid and it is accompanied by symptoms of circumscribed irritation of the peritoneum, especially rigidity of the muscles over the gall-bladder region. Exploratory puncture may be necessary; no harm resulted in the 8 cases in which it was done. The possibility of an abscess in the liver should be borne in mind when there is a history of a stay in tropical regions. Jaundice, especially when intense, speaks against a solitary abscess, but when the liver symptoms have persisted for two weeks or longer the evidence is in favor of a solitary abscess, as the other forms generally prove fatal before this.

May 10, XL, No. 14, pp. 433-464

81 *Normal Blood Pressure in Children. (Praktische Bemerkungen über den Blutdruck und über Normalwerte des Blutdruckes im Kindesalter.) F. Seiler.

May 20, No 15, pp. 465-496

82 *Analeptic Action of Alcohol in Pathologic Conditions. E. Alexandroff.

81. **The Blood Pressure in Children.**—Seiler is convinced that the general practitioner will find the blood pressure an important aid in the diagnosis and prognosis of pathologic conditions in children. He was hampered in his research on the subject by not being able to find any normal standard for the blood pressure in children of different ages and degrees of development, and consequently he has had a table of normal

standards compiled in his service. It represents extensive research and gives the age, the size in centimeters, the weight (with clothing) in kilograms, and the minimal and maximal findings with the Riva-Rocci and the Sahli instruments.

The table states that at the age of 2 and 3, the minimal Riva-Rocci findings range from 70 to 75 and the maximal from 75 to 80; at 4 and 5, minimal from 75 to 85 and maximal from 79 to 90; at 6 and 7, minimal from 72 to 87 and maximal from 85 to 95; at 8 and 9, minimal from 87 to 89 and maximal from 90 to 95; at 10 and 11, minimal from 87 to 90 and maximal from 93 to 96; at 12 and 13, minimal from 84 to 99 and maximal from 94 to 106; at 14 and 15, minimal from 88 to 98 and maximal from 93 to 104; and at 16 and 17, minimal from 95 to 110 and maximal from 103 to 120.

82. **Action of Alcohol During Febrile and Other Pathologic Conditions.**—Alexandroff injected rabbits with diphtheria toxin or other infectious products and followed with injection of alcohol, the results confirming the effect of alcohol as observed in the clinic by Dennig, Hindelang and Grünbaum in respect to the injurious action of alcohol on the circulation during febrile conditions. The alcohol improves the respiration, he found, but this favorable effect is outbalanced by its unfavorable action on the circulation, the blood pressure dropping and the amplitude growing smaller although the pulse-rate may remain the same. The conclusions are that it is necessary to restrict the use of alcohol in febrile states, weighing in each individual case whether the euphoria that follows the use of alcohol outbalances the inevitable somatic injury.

(Das Harnammoniak beim gesunden Menschen unter dem Gesichtspunkt einer ausschliesslich neutralisatorischen Funktion desselben, sowie die Bilanzverhältnisse zwischen Säuren und Alkalien im menschlichen Harn bei verschiedener Ernährung.) W. Klein and F. Moritz.

85. **Variations in Pulse Rate During Standing and Reclining.**—Geigel is convinced that unless the pulse is examined both as the patient stands and reclines the conclusions are liable to be erroneous as the rate may vary by 24 to 72 per cent. as the extremes; the average is under 30 beats. He has notes of the findings in 789 cases, the patients being examined in both positions. As a rule the pulse drops by 12 beats as the individual reclines. Even with exophthalmic goiter the pulse slowed by several beats as the patient reclined. It is his impression that unusually wide variations and acceleration of the pulse on reclining are signs of weakness of the heart. The effort of lying down may accelerate the pulse in some cases; he advises examination for this "negative" behavior on suspicion of heart disease, nephritis or neurasthenia, and urges double examination of the pulse, standing and reclining, in every clinical case.

88. **Action of Epinephrin on the Peripheral Vessels.**—Lichtwitz and Hirsch removed the nerve controlling the vessels in the rabbit's ear and then tested the action of epinephrin on the vessels in this area. In all their experiments intravenous injection of epinephrin elsewhere had an exceptionally intense constricting action on the vessels in the region deprived of its nerves. Their experiments also showed the prompt antagonistic action of amyl nitrite. They suggest as a practical conclusion from their research that the continuous administration of small doses of a suprarenal extract offers prospects for successful treatment of paralysis of the vessels in acute infectious diseases and also in postoperative collapse.

90. **Traumatic Laceration of the Aortic Valve.**—One leaf of the valve was torn but the myocardium developed compensating hypertrophy which prevented serious disturbance from the isolated valvular lesion, permitting full earning capacity with heavy work for ten years when the symptoms of aortic insufficiency became more pronounced. The case is reported as a remarkable example of the way in which the myocardium can adapt itself to pathologic conditions.

100 *Thyroid Weakness and Sugar Hunger. (Schilddrüsenschwäche und Zuckerhunger.) A. Siegmund.

93. **General Anesthesia With Part of the Circulation Shut Off.**—Franke has applied the Esmarch bandage to the thighs or arms or both as a preliminary to chloroform anesthesia, according to Klapp's suggestion, and has been impressed with the advantages of thus shutting off the blood in these regions from the influence of the anesthetic, the anesthesia being induced with much smaller amounts of the drug than with the ordinary technic. The method cannot be used in case of varicose veins or eczema, joint and bone affections; it will evidently have to be restricted to healthy and vigorous limbs, but under these conditions he feels that it is destined to a wide sphere of usefulness, especially for correction of dislocations, fractures, incision of phlegmons and other brief operations. The patients passed under the influence of the chloroform without any phase of agitation and it was rare at any stage of the anesthesia. The breathing was always regular and there was no cyanosis nor salivation; the pulse rate increased a little after the band was applied and again when it was removed, in one case becoming a little irregular for 10 or 20 minutes. There was no vomiting in any case, either before or after the narcosis, and the patients roused in less than 10 or 15 minutes after suspension of the drug. The return to the circulation of the blood overladen with carbon dioxid exerted a pronounced stimulus on the respiration center, evidenced in each case by several deep breaths. There were no complaints of pain from the constriction. The bandage must be inelastic and applied according to Klapp's directions. (They were summarized in THE JOURNAL Oct. 19, 1907, page 1408.) The aim is to shut off as much as possible of both venous and arterial blood; even one leg may answer the purpose. The pulse and general condition and the condition of the limb or limbs excluded from the circulation should be supervised every moment, as with the Momburg belt constriction. A slight transient nervous disturbance was observed in one case in which the band had been left in place for two hours on both legs, and Gräfenberg has recently reported thrombosis in 7 out of 75 cases in which the Klapp technic had been applied. The disturbances proved slight and transient, but they warn that vessels distended with blood are more liable to injury than when the Esmarch bandage is applied to a bloodless limb.

95. **Treatment of Chronic Congestion in the Brain.**—Lots expatiates on the necessity for treating this condition by drawing the blood away from the head while striving to restore and enhance the elasticity of the middle coat of the cerebral arteries. For fifteen years he has been using a method of treatment which he thinks fulfills both conditions and he has recently had occasion to study the mechanism of its action on a young man with a large defect in the skull permitting direct observation of the behavior of the pulse. The treatment includes dry rubbing of the skin over the entire body with a coarse cloth, and trampling barefoot on a pile of fine gravel heated from below. This latter form of application of centripetal stimulation he calls *Kieslaufen*, "gravel

running," and every time it was applied the plethysmographic findings in the instructive case described showed the marked influence of the procedure in reducing the congestion in the head. It may be difficult to distinguish between the symptoms of congestion and those of anemia in the brain; everything that raises the blood pressure and tends to paralyze the middle coat of the arteries increases the disturbances in case of hyperemia in the brain while it reduces them in case of anemia. He warns that a history of syphilis in any case does not necessarily indicate that headache and vertigo are due to "brain syphilis"; they may be the result of simple congestion and mercury and iodid would only aggravate them. His barefoot "gravel running" can be repeated several times a day, up to a half hour each time.

96. **Benefit from Roentgen Rays in Exophthalmic Goiter.**—In the first of the two cases reported by Kuchendorf, part of the enlarged thyroid had been removed on account of cancer but there was prompt inoperable recurrence. Under Roentgen-ray exposures, however, the lesion retrogressed and with it the symptoms of exophthalmic goiter and after a month at Nauheim the patient, a young soldier, reported for duty and has been clinically in good health, with no signs of recurrence during the two years since. The results were equally good in the second case; the patient was a woman who had suffered from progressive symptoms suggestive of exophthalmic goiter for ten years, rebellious to the usual medical measures. As a last resort before thyroidectomy, the Roentgen rays were applied to the thyroid and heart four times each, and the palpitations subsided, as also the profuse sweats; the pulse became regular (78), the circumference of the neck is less by 3 cm. than before treatment, and the eyes no longer protrude so much, while the patient sleeps well and feels well and the dilated heart has returned to a normal outline. The last exposure was in February; whether the benefit attained is permanent or not, it was so striking that he calls attention to the case as suggesting a direct influence of the rays on the cardiac ganglia.

98. **Palpation of the Abdomen.**—Galambos depresses the abdominal wall with one hand, pushing the furrow thus made toward the organ to be examined. This relaxes the wall between the organ and the furrow so that the region is soft and more readily palpated. The hand must be pushed down gently into the depths, and the entire thickness of the wall worked down toward the organ in question. It is possible in this way almost to turn over organs to facilitate palpation.

99. **Milk Secretion in Both the Blazek United Twins After Pregnancy of One.**—See Berlin letter, July 2, page 39.

100. **Thyroid Deficiency and Sugar Hunger.**—Siegmund has encountered some cases in which an inordinate craving for sugar was the most striking sign of defective functioning on the part of the thyroid. He describes two cases in detail, one in a boy under 2, the other in a girl nearly 6. In both cases thyroid treatment restored conditions approximately to normal, emphasizing that the thyroid plays an important part in the sugar metabolism in certain cases. Children with this insatiable craving for sugar tolerate large amounts without the appearance of sugar or albumin in the urine. If thyroid treatment is not practicable they should be allowed all the sugar they crave, as it seems to mitigate the consequences of the thyroid insufficiency and seems to be an arrangement for defense in a certain form of thyroid weakness. The older child had suffered for years from severe diarrhea and was extremely debilitated; by the sixth day of thyroid treatment she walked several miles without fatigue, while the appetite became normal. He sometimes gave suprarenal juice in the place of the thyroid extract, finding that this advantageously supplemented the other. The benefit was equally striking in the second case, the children becoming absolutely transformed under the thyroid treatment.

110 The Cobra-Venom Hemolytic Reaction. (Ueber die Kobragifthämolyse und die Much-Holzmannsche Psychoreaktion.) H. Selter and A. H. Hübner.

101. **Gonorrheal Epididymitis.**—Bruck expatiates on the importance of wearing a suspensory during gonorrhea and refraining from any excess which might aggravate the infection and lead to posterior urethritis. This is the more important as the majority of cases of epididymitis follow gonorrhea with inadequate treatment. The article issues from the university clinic at Breslau in charge of Neisser. In every case of acute febrile painful epididymitis the scrotum is sterilized with tincture of iodin and the tunica propria is incised; this relieves the pain at once and evacuates existing fluid. An alcohol dressing is then applied and if the fever subsides after a day or two gonococcus vaccine treatment is then instituted; this is especially useful in gonorrheal arthritis and epididymitis. The results have been particularly good in 50 cases of the latter. If there is no fever the tunica is not incised and the vaccine injection is made at once accompanying the first alcohol dressing. If the nodules do not subside, hot sand packs are applied for a few days to hasten absorption; if these fail, a dressing of adhesive plaster generally accomplishes the desired purpose. It is also the practice to give 3 mg. of atropin daily in every case of acute posterior gonorrheal infection to keep the prostate, seminal vesicles, etc., quiet and prevent dangerous retrograde movements. Even with already existing unilateral epididymitis, smaller doses up to 1 mg. daily are given for several days. This prophylaxis is not absolutely reliable, he remarks, but even if it succeeds in only a few cases the measure is justified as sterility is said to follow unilateral epididymitis in 40 per cent. of the cases and in 90 per cent. of the bilateral cases.

108. **The Skin Trephine.**—Richter has found extremely useful a small cylinder with a cutting edge. By twisting the cutting edge into the summit of a furuncle or other focus, the little disc of skin thus cut is easily removed and the scar left is minimal. This little skin trephine is also useful for obtaining blood for clinical diagnosis. He supplements the use of the trephine with a suction apparatus when the plug does not come away at once.

118 Intravenous General Anesthesia. (Zur Frage der intravenösen Narkose.) P. Sick.
119 *Prophylaxis of Uterine Cancer. (Gebärmutterkrebs und Aufklärung des Publikums.) F. Müller.

111. **Instrumental Dilatation of the Uterine Cervix.**—Bossi compares the various methods for rapid emptying of the uterus and states that nineteen years' experience with his metal bladed dilator has demonstrated that this method can be applied in nearly every case, even when there has been no change in the cervical passage, and without necessity for an assistant. The dilator has a natural labor-promoting effect as well as a mechanical action as it stimulates natural labor

contractions; but the obstetrician is not subject to Nature's caprices; with the steel dilator he is her *master*. *The liability to laceration is the only objection to the method*, and this injury is rare when the gravity of the cases demanding the rapid emptying of the uterus is taken into consideration. Even with spontaneous and forceps deliveries, he remarks, laceration *is liable to occur, and cervical incisions* cause deeper and certain lesions and danger of laceration of the uterus. *None of* the dilators in vogue has proved any improvement, he declares, over his original dilator, but it must be used strictly *according to his directions, introduced* under the guidance of the fingers, the fingers guarding the cervix while the dilator is in place: the blades should be spread only very gradually, and only during a pause between the labor contractions. He has applied the dilator in 480 cases and 454 of the mothers were saved and all but 60 of the children. The main point is to refrain from haste, except in extreme emergencies. He takes from 15 minutes to an hour and a half to dilate the cervical canal sufficiently for extraction of the child. This he does generally with forceps and at once; the cervix dilated in this way is liable to contract soon again. Chloroform can be given, he says, without harm, and general anesthesia is directly indicated in eclampsia requiring rapid emptying of the uterus. *If the forcible dilatation is to be merely preliminary to spontaneous delivery*, he places the patient in a *horizontal position after a few energetic contractions have been observed and holds the dilator in place* with a bandage, spreading the branches a trifle occasionally to keep up the stimulus, and removing the instrument when delivery is impending, replacing it if the contractions become weak again.

118. **Superheated Air in Treatment of Erysipelas.**—Ritter has applied the hot-air douche in treatment in 19 cases of erysipelas and states that the rapid recovery was *striking*. *The jet of superheated air* was applied to the spot for half an hour to an hour two or three times a day. Absorption is promoted to such an extent that there is generally a slight rise of temperature afterward. The lesions were usually on the face and neck; when other parts of the body were involved he used the hot-air box or chamber (or a hot flat-iron).

119. **Prophylaxis of Uterine Cancer.**—Müller gives an illustration of a *circular* which he hands to every patient and has printed on the back of the certificates, etc., he makes out. It states in display type that every woman should apply to a physician at once for examination in case of irregular bleeding, especially after marital intercourse and during the change of *life* and afterward, *and in case of an ill-smelling discharge that looks* like water in which meat has been rinsed. The text concludes with the statement that cancer of the womb is permanently curable *but only* by an operation done at the right time; that is, when the patient applies to a physician as early as possible.

Therapeutische Monatshefte, Berlin

May, XXIV, No. 5, pp. 225-280

120 *Importance of Absolute Repose in Treatment of Pneumonia. (Zur Behandlung der [illegible] Volland.
121 Importance of Silence ir [illegible] Tuberculosis. (Zur Schweigebehand... [illegible] kulose.) E. Ebstein.
122 *Scabies and Nephritis. Braune.
123 *Operative Treatment of Diffuse Meningitis. G. Krebs.
124 *Treatment of Spasm *of the Glottis by* Exclusion of Milk from the Diet. (Behandlung des Stimmritzenkrampfes mit kuhmilchfreier Ernährung.) F. Fischbein and L. Langstein.
125 Behavior of Peroxids in the Gastrointestinal Tract. (Verhalten der Superoxyde im Verdauungstrakt.) K. Boas.
126 *Indications for Mercurial Treatment in Simple Atrophy of the Optic Nerve. (Indikation für die Quecksilberbehandlung bei der einfachen Sehnervenatrophie.) Schultz-Zehden.

120. **Absolute Repose in Treatment of Pneumonia.**—Volland has been teaching since 1893 the importance of absolute bed rest in the dorsal decubitus in pneumonia and pleurisy and declares that both theory and practice confirm the great value of this measure. He does not have the patient move at all and does not let him sit up even to be examined, not wishing to allow the weight of the consolidated lung to drag down on the diaphragm or pull on the sound parts of the lung. The pneumonic lobe loses all its elasticity and acts like a heavy weight, traction from which is liable to do serious harm to the blood and lymph vessels and to the air cells. He thinks the physician can judge of the case well enough without the *necessity for thorough physical* examination of the lungs. As the patient lies on his back the inflamed part of the lung has a firm support against the rear wall of the thorax and the patient feels easier in this position. Treatment should aim to relieve pain, promote expectoration but reduce the impulse to cough, keep the fever down with local cold applications and stimulate the heart at need.

122. **Scabies and Nephritis.**—Braune encountered three cases of *nephritis* accompanying scabies and discusses whether there is a causal connection between them or between the nephritis and the beta-napthol or balsam of Peru used in treatment of the scabies. In these and in a number of similar cases in the literature the nephritis did not develop until after the scabies had entered an eczematous stage. It seems *probable that the scabies* is able to aggravate an already existing nephritis but the matter is still obscure, and he urges systematic examination of the urine before, during and after treatment of the scabies in order to get an insight into the factors responsible for the nephritis.

123. **Operative Treatment of Diffuse Meningitis.**—Krebs' patient was a woman of 34 who developed middle ear disease with an insidious onset and perforation of the tympanic membrane by the end of three months. A large extradural abscess was evacuated two weeks later but symptoms followed typical of internal ear disease and meningitis, rapidly progressing to paralysis and coma and the patient was apparently moribund. The middle cranial fossa was opened and then the posterior; the cortex was congested and swollen but no suppuration could be found; on account of a tendency to hemorrhage from the sinus petrosus no attempt was made to open into the labyrinth. *The meningitic symptoms rapidly* subsided and recovery was soon complete. The case is cited as encouraging operative treatment in every case of meningitis *originating in middle ear disease* when the pulse and *respiration permit the hope that the patient will leave the table alive.* The case further warns that the findings in the cerebrospinal fluid are liable to be misleading and that lumbar puncture may be dangerous, as withdrawal of 2 or 3 c.c. of a slightly turbid fluid, which dripped slowly, was followed by *immediate collapse requiring six hours of active measures for resuscitation.* Kümmell has reported a case of traumatic meningitis with the fluid like thick pus and yet the patient recovered. Schlesinger has reported a case in which the meningitis became worse after lumbar puncture. Krebs lost three patients while waiting after exposure of the dura; he now makes a practice of incising the dura at once if there are signs of pronounced meningitis. The opening must be *ample*; hernia of the brain is equally liable with a small as with a large incision, so he makes a large crucial incision and on suspicion of an abscess in the brain inserts the *scalpel* at several points in the temporal lobe and cerebellum. He did not change the dressings for a week in the case reported. Saline transfusion of 500 gm. was made before and after the operation. The patient was discharged cured in three weeks but the pulse persisted small and fast for months longer.

124. **Treatment of Spasmophilia by Excluding Cow's Milk from the Diet.**—Fischbein insists anew that the *change from cow's milk to a carbohydrate, starch diet is often a* life-saving measure with spasm of the glottis and general convulsions in the spasmophilic diathesis. He asserts that the prompt influence from this change in diet may differentiate disturbances from this cause when the symptoms *otherwise* suggest meningitis or otitis media. It is also useful in controlling the spasms in whooping-cough. Langstein warns, however, that the starch diet may have a pernicious effect with infants suffering from severe gastrointestinal disturbances. Breast milk is alone permissible in these cases. He doubts further whether the spasms in whooping-cough are *amenable* to this measure although conceding that they generally develop on the basis of the spasmophilic diathesis. Eckert has reported excellent results from lumbar puncture.

126. **Mercurial Treatment of Atrophy of the Optic Nerve.**—Schultz-Zehden reviews what has been written *on* experi-

mental and clinical injury of peripheral nerves by mercury, especially injury of the optic nerve, and then relates his experiences with mercury in treatment of atrophy of the optic nerve with and without an organic nervous affection. His conclusions are all in favor of a mild cautious course of mercurial treatment in simple atrophy of the optic nerve, and above all when there is a history of syphilis and the optic atrophy is the only symptom. Remission of the symptoms in tabes may also be realized under mercurial treatment if there is a history of syphilis, the Wassermann reaction positive or, if negative, a history of inadequate specific treatment, and when the state of nourishment and absence of physical and mental stress augur well for the treatment. The dosage should be mild and cautious, never pushing the mercury, and the field of vision and visual acumen should be constantly supervised.

June 4, No. 23, pp. 793-816

141 *Improved Technic for Nephropexy. (Zur Operationsmethodik der Nephropexie.) L. Casper.

139. **Therapeutic Displacement of Enlarged Thyroid.**—In the case reported by Arnd, the left half of the goiter with the parathyroids had been removed, but mechanical disturbances persisted and increased, the lower right half compressing the trachea. Its operative removal seemed hazardous on account of possible injury to the remaining parathyroids. Arnd separated the enlarged thyroid from the trachea and ligated the superior artery. He then separated the sternomastoid from the cleidomastoid upward from the clavicle and pushed the smooth thyroid tumor through the resulting slit. It pushed through readily and was held firmly by the muscles without suturing.

140. **Etiology of Traumatic Ossifying Myositis.**—Ewald suggests that possibly the synovia forced into an adjacent broad leshy muscle by the trauma may be responsible for starting he ossifying process. It seems to develop only under such ircumstances.

141. **Nephropexy.**—Casper incises the fibrous capsule and hells the kidney out of its adipose capsule. He then pushes he capsule back and down, cutting it off about 1 cm. from the hilus in front, and cutting off the upper half in the rear. The remaining rear half of the fibrous capsule is then folded together and sutured to the quadratus lumborum in such a way that the upper part of the kidney, or at least half of it, is brought beneath the costal arch. No suture is passed through the parenchyma of the kidney, but the two through the fibrous capsule sustain the kidney until adhesions develop between its rear raw surface and the quadratus lumborum and the front raw surface and the abdominal wall. He has performed this operation for wandering kidney in 19 cases, and for nephritis causing anuria, colics or hematuria in 10 other cases. One patient with extremely contracted kidney died. In all the other cases the kidney grew solidly to its environment.

144 Improved Laparotomy Retractor. (Neuer Bauchdeckenhalter.) [illegible]
145 [illegible] of Eclampsia. (Zur Theorie der [illegible] J. Thies.
146 *[illegible] in Treatment of Eclampsia. W. [illegible]
147 *Recovery from Puerperal Eclampsia After Decapsulation of the Kidney. (Ein durch Nierendekapsulation geheilter Fall von puerperaler Eklampsie.) K. Baisch.
148 *Isolation of Stumps of Uterine Adnexa in Laparotomies for Gynecologic Disease. (Neue Technik bein gynäkologischen Laparotomien.) E. Solms.
149 Obstetric Rachiotomy Superior to Decapitation. (Rhachiotomie—Rhachioklast.) V. Caliri.

146. **Prophylactic Method of Treating Eclampsia.**—Stroganoff reaffirms the efficacy of his method of treating eclampsia by keeping the patients under the influence of morphin, chloral and chloroform, with heat applied to feet and kidney region, milk by the rectum or mouth, and avoidance of any irritation. The details of his method were given in The Journal, July 3, 1909, page 86, and Sept. 20, 1902, page 733. The mortality of the mothers has been 6.6 per cent. and of the children 21.6 per cent. in the 400 cases of eclampsia in which this method has been followed. He here describes his experience with it in some test cases at Vienna, urging that its systematic application would reduce the mortality below 2 per cent. as he has done in several long series of cases, without any necessity for hastening delivery or for decapsulation of the kidney.

147. **Decapsulation of the Kidney in Eclampsia.**—Baisch commends decapsulation of the kidney as the most potent and reliable means of stimulating diuresis at our command. In a case reported in detail the primipara was apparently moribund; the eclamptic seizures, coming on after spontaneous delivery, were so severe that artificial respiration was required for a long time after each; the pulse was soon 120 to 130, the blood pressure 150 mm. and only 248 c.c. of urine with albumin 15 per thousand, were obtained in 19 hours. There were no further seizures after the decapsulation and the coma subsided at once; by night 400 c.c. urine with 3 per thousand albumin had been passed.

148. **"Isolation of the Stumps" of the Adnexa.**—Solms draws the stumps down into the small pelvis and shuts off the open abdominal cavity completely, providing for drainage at need with openings in the front and rear roof of the vagina. The fundus of the uterus is drawn over forward and fastened to the vaginal wall, incised for the purpose. The technic insures that all raw parts are excluded from the peritoneal cavity, and the secretions from the isolated stumps are drained away into the vagina. He says that the method can be applied to the uterus also after myomectomy, etc., and that it obviates danger of infection of the peritoneum from any processes in the genitalia.

151 *Combined Oxygen-Epinephrin Inhalation Method of Treatment of Bronchial Asthma. (Sauerstoff-Adrenalintherapie des Asthma bronchiale.) J. Segel.

151. **Oxygen-Epinephrin Treatment of Bronchial Asthma.**—Segel has an arrangement by which the patient inhales oxygen mixed with 1 c.c. of a 1 per thousand solution of epinephrin and reports two cases in which these inhalations promptly cured severe bronchial asthma, persisting since early childhood, refractory to all other therapeutic measures. *The combined oxygen-epinephrin treatment gave remarkable relief in one or two applications and after thirty in the course of two months the cure seems to be complete.* The first patient was a woman of 51, the other a girl of 16. *A single sitting was followed by a night free from asthma, for the first time in years.* The second patient is still taking one sitting a week. He declares *that this simple inhalation method justifies the strongest hopes, and it should certainly be given a trial.* He experimented with it on himself for weeks until convinced that the combined oxygen-epinephrin inhalations were free from any influence on the blood pressure and untoward by-effects.

156 Experimental Research on Defensive Action of Constriction Hyperemia. (Ricerche sulla azione difensiva della stasi.) M. Almagia and R. Tata.

153. **Acetic-Acid Seroreaction.**—Rivalta published in 1904 a method of distinguishing between transudates and exudates *by the precipitation of the globulins in the fluid by a weak solution of acetic acid.* If a drop of the fluid to be examined is dropped into a glass containing 100 c.c. of water with which two drops of glacial acetic acid have been mixed, the drop of organic fluid leaves a trail like a little smoke as it sinks down through the water. He now announces that this test slightly modified can be used for the diagnosis and prognosis in various conditions, *the positive reaction in an extremely weak dilution of the acetic acid indicating the resisting powers of the organism, as estimated by the ability to produce globulins.* In health serum gives the reaction at 1: 150 or 1: 300 but in *pneumonia the figures were 1: 400 up to 1: 2500; in 19 cases of typhoid up to 1: 900.* The lower the figure the graver the prognosis as a rule, the increase of the globulins *in the blood showing the active processes of defense going on.* He describes the technic for both the serum and the blood test, but the former is simpler. While the blood is clotting, he mixes one drop of a saturated solution of sodium *carbonate* with 100 c.c. of *distilled water, and in another* glass two drops of glacial acetic acid with 100 c.c. of distilled water. Then 0.5 c.c. of the serum is transferred to a test tube which is then filled to 10 c.c. with the sodium carbonate solution. This is the mother serum solution, and a drop is taken on a glass rod, held vertically, and transferred to the acetic-acid solution; it drops from the rod in the form of a white ring, best seen by artificial light. The serum is *diluted again* and again to determine the extreme limits of the reaction. He relates his experiences with it in a number of cases.

THE RÔLE OF PEDIATRICS IN PREVENTIVE MEDICINE*

THOMAS S. SOUTHWORTH, M.D.
NEW YORK

Since my paper deals with no narrow specialty, but one which involves the application to youthful subjects of all the rapidly growing wealth of medical knowledge, I am aware that it will be a difficult matter to present the rôle of pediatrics in preventive medicine without trenching somewhat on the field of other speakers. As a specialty, it can scarcely be said to have been recognized in this country before the creation of a separate department for our distinguished colleague, Dr. Jacobi, at the College of Physicians and Surgeons of New York, in the year 1860. Before that time, and too largely thereafter, it was linked to obstetrics and diseases of women, with which subjects it had only a quasi connection, and in consequence its study was contracted and neglected. Having broken its bonds, however, and emerged from overshadowing obscurity, pediatrics to-day stands for the application of the same scientific methods of investigation to the immature organism of the child and the diseases to which it is liable, as are applied to the study of similar processes during mature adult life and the subsequent period of gradual senescent decay.

Nevertheless, although often referred to and practiced as a specialty, pediatrics belongs, not to the few, but essentially to all practitioners of medicine, for they, rather than the specialist, are called on to apply its teachings in family practice to the vast majority of infants and children.

To distort somewhat a well-known saying of Dr. Oliver Wendell Holmes, let me advance the view that preventive medicine, as applied to the child, should begin with the grandparents. Since, however, this carries me somewhat beyond the limits of the subject assigned to me, I must perforce begin with the birth of the child. Even at this starting point, the pediatrist finds himself disputing the territory at both ends of the social scale—at one end with the midwife, and at the other with the obstetrician. Great as is the disparity between both the knowledge and equipment of these two groups who assist in ushering infancy into this inhospitable world, suffice it to say that there is a growing feeling that greater effort should be made by both groups to secure maternal nursing, because their tenure of the field is sufficiently long to determine, often irreparably, the mode of the infant's nourishment. If breast feeding has been unnecessarily rejected, the pediatrist, when called in, must make the best of the situation as he finds it, but he cannot always retrieve the error. However, since in the majority of cases the family physician conducts the confinement and also subsequently cares for the child, we may assume that pediatric teaching governs the management of the infant from birth.

First and foremost, pediatrics deals with the nutrition of the infant, for unless it lives, science can do nothing further for its welfare. Aside from reasonable hygiene which so many healthy infants seem surprisingly able to do without, the first step in the preservation of life is suitable food. As the majority fed at the breast thrive and the more vulnerable among the infants were found among those artificially fed, early attention was inevitably centered on substitute feeding. Since cows' milk was the best available substitute for breast milk, every effort was made to render it more suitable.

The discovery of teeming myriads of bacteria in commercial milk led Soxhlet to propose sterilization, in the belief that to bacteria were due the noxious effects of cows' milk on the digestive tract of the infant. Pasteurization followed as an improved method of killing, but not necessarily rendering innocuous, the masses of bacteria with their toxins which abound in ordinary milk. Then followed the triumph of pediatric endeavor in the inauguration of the movement, destined to be world-wide, for the production of clean milk, the laurels of which we willingly share with other workers who have helped to make it a possibility. This work must suffer no abatement. Milk, fresh and uncontaminated, must be produced in increasing quantities for the use of all young children, yet even recently there have appeared those who, tinctured with commercialism and ignoring all other factors, have claimed for Pasteurization all that has been accomplished in the reduction of infant mortality. From the pediatric standpoint, the rôle of Pasteurization is and ever should be, to keep clean milk sweet until it is consumed, never merely to render a filthy milk somewhat less dangerous.

During the past decade, pediatric investigators have been restlessly and energetically active in perfecting infant feeding. The belief once cherished that an exact counterpart of human milk might be made from cows' milk was quickly shattered. Although normal infants throve in greater numbers on such mixtures, it was found that they must be adapted to the inexperience, the age, and the idiosyncracies of the individual infant. For such adaptations, rules of great value were formulated and proved, yet for the less normal digestions further studies seemed necessary. As a result, the theoretical structure on which infant feeding was first based has been torn down and rebuilt. The proteins, fats, and latterly the sugars and carbohydrates entering into the composition of bottle feedings, have been scrutinized, tested, and adjusted. As a consequence, it may now be confidently stated that the infant, fed intelligently according to modern American methods, has to-day a better chance both of life and well-rounded development than ever before in our history.

---

* Read in the Section on Preventive Medicine and Public Health of the American Medical Association, at the Sixty-first Annual Session, held at St. Louis, June, 1910.

As has been indicated, the purpose of nutrition is not only to preserve life, but to produce an uninterrupted and well-balanced development of the body. Gain in weight alone is not all that is required. Nature, as a rule, strives to do her work well, and if the conditions are favorable slights no part of it. But no workman can build well unless liberally supplied with proper material. The infant fed on condensed milk, for example, may be fat and apparently healthy, but Nature has been forced to do scamped work. In the usual dilutions, condensed milk is low in protein, lower in fat, and overrich in sugar. Such one-sided nutrition produces a development poorly fitted to withstand the effects of illness. Let it not be understood that this form of feeding is chiefly culpable. All artificial feeding holds this danger, partly because of its composition, partly because of the limitations of different infants in the digestion and absorption of individual elements in any food which replaces the natural breast milk. Such malnutrition, in greater or lesser degree, accompanies the ignorant home feeding, the carefully or carelessly yet faultily composed formulæ of many medical men, and the "just as good" substitutes of the patent-food makers. It is sometimes a question in my mind whether those errors of nutrition which are of lesser degree do not in their total produce more harm, since they are more frequent, less commonly detected, yet equally liable to leave their marks in some degree on their victims.

On the other hand, a body developed through proper, well-balanced nutrition, is not only less susceptible to diseases caused by bacterial invasion, but, if such occur, is better able to throw them off, and less liable to complications. When we realize the part played, not only by complications but by the other direct and indirect results of malnutrition in swelling the mortality figures among young children, the prophylactic importance of proper nutrition, in producing increased resistance becomes evident. Since we must all realize that the sturdy child possesses greater powers of protection and recuperation, it would hardly seem necessary to defend this premise; nevertheless innumerable instances of the effects of malnutrition present themselves to our minds.

With the marasmic infants digestive action is crippled; assimilation below par; slight errors in diet cause further disturbance; pulmonary diseases are readily acquired; hypostatic pneumonia is almost a specialty; furunculosis of a severe and debilitating type is not uncommon; suppurative conditions show little or no tendency to repair; the middle ear becomes affected on slight provocation; in the hot months, summer diarrheas more than decimate their ranks.

Rachitis, another form of malnutrition, varies so widely in the degree and distribution of its manifestations, that the claim so often made that it is present in the large majority of bottle-fed infants seems to be substantiated when careful search is made. The classical bone changes, important as they are, do not manifest the sole incidence of this common affection. The ligaments, the muscles, the nervous system, the respiratory tract and the intestine may likewise be affected and contribute to the symptomatology. Aside from such bone deformities as may influence the patient's appearance and bearing in later life, those of the thorax and pelvis are the most serious—the former increasing both the liability to and the danger from pulmonary disease; the latter, in the female, menacing in later years the life of both mother and child during parturition. The undeveloped musculature of the rachitic child, causing him to creep long after he should have walked, keeps him longer exposed to the dust and draughts of the floor, and deprives him of normal exercise, which plays such an important part in healthy development. The underfed and unstable nervous system contributes through convulsions and laryngismus its own quota of danger, not only of death, but also of lasting paralysis if there be hemorrhage at the time of the seizures. The relaxed and disturbed intestinal tract of the rachitic furnishes frequently a favorable field for the development of serious enteric affections.

The third of this group, infantile scurvy, is happily so uncommon as to play a smaller part in infant morbidity and mortality than the other forms of malnutrition, but its comparative rarity increases the danger that it may not be recognized and receive appropriate treatment. No affection of infancy can, however, be traced with greater certainty to some deficiency in the elements of nutrition, and its increasing frequency from the too exclusive and prolonged use of proprietary foods warns us to be alert in its detection.

The pediatrist has a further important rôle, as the adviser of the mother in the care of her children. All that may be summed up under the comprehensive term hygiene is taught her either in answer to her questions or through the medium of the printed page. The influence of bathing, clothing, fresh air, exercise, and hours of sleep, in the building of a resistant body and in the prevention of disease, together with the necessity for their nice adaptation to the differing periods of infancy and childhood, need only to be mentioned to this audience to be appreciated.

It is also the privilege of the children's physician not only to treat disease, but to foresee and prevent it. Simple as seems this statement, an incalculable amount of benefit can be bestowed on humanity in this way. Aside from the countless ills which can be prevented by proper management of the feeding, anemia must be recognized and treated if the child is to escape the severer effects of the acute infectious diseases. Rachitis, already mentioned, which the parent invariably overlooks until its effects are marked and possibly irremediable, must be detected and checked. The prophylactic care of the teeth, so commonly neglected because of the division of responsibility with the dental surgeon, should be insisted on from their earliest eruption. Adenoids and hypertrophied tonsils, which are rarely brought to the attention of the throat specialist until they have already wrought injury to the child in one or more directions, should be recognized and removed. The popular view, so often advanced, that adenoids and tonsils will be outgrown, or that it is scarcely worth while to remove them since they may later recur, is, without question, the echo of evasive statements made by physicians, who, feeling themselves incompetent to perform these simple operations, were the more willing to defer them indefinitely.

In direct opposition to the views of certain rhinologic colleagues, I believe that the early removal of adenoid obstruction to nasal breathing favors the normal use and consequent expansion of the nasal passages, and lessens very materially the probability of the occurrence of those chronic hypertrophic obstructions within the nose which later make the removal of the adenoids ineffective in restoring nasal breathing. He believes that the view of the rhinologists, that conditions other than the adenoid are responsible for a large proportion of the mouth-breathers, is due to the late age at which they see these patients, and that the opportunity to operate more frequently during the first and second years would soon cause a modification of their views.

Nor does our interest and supervision cease when the child passes from the home to the school, or, in the case of the less fortunate, to the workshop or the factory. Behind the educator, the inspector and the reformer, stands the pediatrist, who, from his more intimate knowledge of the child's development and limitations, directs their enlightened efforts for the betterment of conditions in these fields.

I have endeavored to outline briefly in the foregoing remarks the lamentable results of neglect, and the enormous opportunities of the pediatrist if he exerts a wise control over the growing organism of the child. The trite phrase that "as the twig is bent, the tree's inclined," had never truer application than to the youthful body. Pediatrics has reduced to a science this formative period of human life. Endless possibilities pertain to the conscientious application of our knowledge.

Extensive as is the debt which we owe to the laboratory and to the co-operation of other specialties, gratefully as we acknowledge their aid in combating disease and in insuring to the rising generation a better equipment for their struggle, nevertheless, the earliest and the ultimate responsibility falls on the children's physician, for to his hands they are confided by their parents, and on his judgment reliance is placed, not only to deal with the present, but to detect and remedy conditions and tendencies ere they assume a harmful or serious phase.

807 Madison Avenue.

THE NOGUCHI SERUM REACTION FOR SYPHILIS AS AN AID TO DIAGNOIS IN EYE LESIONS*

ALBERT E. BULSON, JR., B.S., M.D.
Professor of Ophthalmology in the Indiana University School of Medicine
FORT WAYNE, IND.

The serum diagnosis of syphilis as given to the world by Wassermann, Neisser and Brück[1] in 1906, has now become a well-established diagnostic method, generally used in all medical centers, and has proved of value in all fields of medicine.

The Wassermann method is an adaptation of the Bordet-Gengou phenomenon of complement deviation, in which the hemolytic system consists of a suspension of washed red blood cells of the sheep, hemolytic amboceptor made by immunizing rabbits to sheep's red blood cells, and as complement fresh guinea-pig serum. For syphilitic antibody the serum from suspected patients is used, and for antigen a watery extract of a liver of congenital syphilis known to be rich in *Spirochæta pallida.*

It has been pointed out that there is one factor of error in this method due to the fact that there is in human serum a variable amount of natural antisheep amboceptor which tends to produce hemolysis and hence a negative reaction in the presence of the smaller amounts of syphilitic antibody. To avoid this error Noguchi[2] has proposed a change in the hemolytic system. His modification consists in using human red blood cells, with antihuman serum from rabbits, instead of sheep's cells and hemolytic serum from rabbits as used by Wassermann. By the use of this antihuman hemolytic system the variable antisheep amboceptor of human serum is eliminated as a disturbing factor. Noguchi has also found it possible to prepare antigen, antihuman hemolytic amboceptor and guinea-pig complement, in the form of reagent papers which remain fairly stable so long as kept perfectly dry, thus simplifying the method without any sacrifice in accuracy. His views regarding the use of complement dried in paper have been modified within the past few months and now he considers it advisable to use the liquid complement whenever possible, the use of complement in paper to be reserved for emergencies.

The technic of the test is described in detail in Noguchi's work[3] and is quoted in brief as follows:

> Only about 2 c.c. of the patient's blood is needed and this may be obtained by puncturing the index-finger or lobe of the ear and collecting the blood in a small glass tube. The blood-clots and the serum separate in a few hours at room temperature. If the test is not to be made within two or three days the serum should be drawn off with a capillary pipette for storage.
>
> The corpuscle suspension can be prepared with the blood of a normal person. The blood is allowed to drop into a test-tube of salt solution. The proportion should be one drop for each 4 c.c. The quantity of the suspension thus prepared is enough for one complete test, with some left over in case it is necessary to repeat the test. The suspension must be allowed to stand over night in a cool place; or is centrifugalized soon after collection, to separate the cells. The supernatant fluid is carefully poured off and replaced with a fresh salt solution and a suspension made by shaking. This operation removes the serum constituents, and especially the fibrin ferment, which often disturb the test. A 1 per cent. suspension of the washed corpuscles should be used.
>
> To facilitate the carrying out of the test a rack containing two rows of holes for the tubes should be used. For each test two tubes are required, one in the front row and its control in the rear row. There will also be two pairs of tubes to serve as positive and negative controls.
>
> Put into each of two small test-tubes, front and rear, one drop (about 0.02 c.c.) of the serum to be tested from a capillary pipette. Add to each tube 0.1 c.c. of 40 per cent. fresh guinea-pig serum made by adding 1 part of complement to 1½ parts of 0.9 per cent. salt solution. In an emergency or where fresh complement cannot be obtained dried slips of paper, each containing two units of complement, may be substituted. To the front tube add the slip bearing the antigen. Then to both tubes add 1 c.c. of the 1 per cent. suspension of washed human corpuscles. Shake the tubes thoroughly from time to time to distribute the reagents evenly throughout the mixture as they dissolve out of the paper.
>
> With every series of tests it is necessary to carry out two sets of controls, and for this purpose four additional tubes will be necessary. To each of the first pair of these, one in the front and one in the rear row, is added one capillary drop of a syphilitic serum known to give a positive reaction. This will serve as a positive control. To the second pair add one drop of normal serum known to give a negative reaction; or the tubes may be left empty. This pair of tubes will serve as a negative control. Now put into each tube complement and into the tubes of the front row only antigen, adding finally 1 c.c. of the corpuscle suspension to each tube.
>
> Place the rack holding these pairs of tubes in a water-bath, thermostat, or warm place not over 37 C. The vest-pocket is warm enough and convenient in an emergency when none of the above is at hand. Allow an hour from the time the mixture is made for the antibody to combine with the antigen and for complement to be fixed. If a water-bath is used, thirty minutes is a sufficient length of time. If dried paper complement

---

* Read in the Section on Ophthalmology of the American Medical Association, at the Sixty-first Annual Session, held at St. Louis, June, 1910.

[3] Noguchi: Serum Diagnosis of Syphilis, J. B. Lippincott, 1910

is used this period of incubation should be extended to twice as long as is the case when liquid complement is used. The contents of the tube are as follows:

Rear: Test serum + complm. (2 units) + 0 + corpuscle susp. 1 c.c.

Front: Test serum + complm. (2 units) + antigen + corpuscle susp. 1 c.c.

First incubation at 37 C. for one hour; then add to each tube, both front and rear, a slip bearing two units of amboceptor. Allow another two hours in the thermostat or one hour in water-bath. After final incubation the tubes should be kept at room temperature for a few hours before the results are recorded.

It is necessary to make certain that the tests in the control sets have been properly carried out. The pair of tubes containing normal serum (or without any serum) must be completely hemolyzed. These constitute the negative controls and show that the hemolytic system used is effective, and that the amount of antigen used is not by itself inhibitory of hemolysis. Next, the front tube of the positive control set, containing a known syphilitic serum, must show total inhibition of hemolysis, while the rear tube must show complete hemolysis. Thus we are certain by the rear tube that the syphilitic serum itself does not inhibit hemolysis, while the front tube, in which hemolysis is inhibited, shows the ability of syphilitic antibody to fix complement in the presence of the antigen employed.

These essentials having been fulfilled, the tubes containing serum for diagnosis can be scrutinized. In these tests hemolysis must be complete in the rear row, since antigen is not present and the amount of serum used should not be inhibitory. Should hemolysis be inhibited markedly, showing usually an anticomplementary action on the part of the patient's serum, this may be overcome by "inactivation" of the serum for thirty minutes at 56 C. (before commencing), after which it will be necessary to use four to five drops of the serum in the test. The time of inactivation for this purpose may be shortened to fifteen minutes (instead of thirty minutes) and three drops of the serum used in this instance. The anticomplementary action can be overcome also by the use of a larger dose of complement. In case inhibition is only slight in amount, the addition of 0.15 to 0.20 c.c. of a 40 per cent. complement mixture (mentioned already) can be used. The above irregularities are occasionally encountered in the test, especially during the summer months.

The tubes containing the serum for diagnosis and antigen, the front row of tubes, may be examined for final results. Here any degree of hemolysis may be encountered, from total inhibition to complete dissolution of corpuscles, depending on the presence or absence of syphilitic antibodies and the number of antibody units. With complete inhibition of hemolysis, the end reaction is easily interpreted, the corpuscles settling to the bottom of the tube with the clear salt solution above. Complete hemolysis likewise gives a result easy of interpretation, for the corpuscle mass is entirely dissolved, the hemoglobin going into solution and coloring the salt solution a deep reddish color.

By taking into consideration the bulk of corpuscles settling to the bottom of the tube and the amount of tinting of the supernatant salt solution, and by comparison with the positive and negative controls, the varying degrees of inhibition of hemolysis may be ascertained. In interpreting the result complete inhibition of hemolysis comparable with the positive control is called strongly positive; complete hemolysis, comparable with the negative control, is designated as a negative reaction. If 60 to 70 per cent. of the bulk of corpuscles is dissolved the reaction is doubtful and should not be taken into consideration for diagnosis. In a known specific case such slight inhibition should be an indication for further treatment as evidence of the continued presence of syphilitic antibodies in the patient's blood. If there is a faint degree of hemolysis, the main bulk of corpuscles being intact, the reaction should be called positive. A more intense hemolysis, with about 10 to 20 per cent. dissolution of the corpuscle mass, should be called weakly positive, while 30 to 40 per cent. hemolysis is designated as faintly positive. Neither the weakly positive nor the faintly positive reaction should be accepted as a definite diagnosis of syphilis without the presence of strong clinical evidence in favor of such a diagnosis. In case the reaction should be doubtful, the serum should be reexamined after a period of a week has elapsed, and if necessary several examinations in succession should be made. In all cases it is a wise precaution to take the blood for examination shortly before meal-time.

It may be stated here that all human serums gradually become anticomplementary after several days on standing, some more pronouncedly so than others. This change sets in much more rapidly at a higher temperature, such as that of a room, than at a lower temperature, such as that of a refrigerator.

In order to have a positive control test, whenever examining an unknown serum one must always have at hand a syphilitic serum known to give a positive reaction. For this purpose one has to obtain a good specimen, which can be preserved on ice for months. Should such a specimen become too anticomplementary on standing, one can remove this property by heating the serum at 55—56 C. for about fifteen minutes.

The method of titrating the antibody content of syphilitic serum in order to determine the exact strength of each specimen is fully described by Noguchi, as also the manner of preparing slips. Guinea-pig serum is used as complement and this should be used fresh, as after the serum is forty-eight to seventy-two hours old its activity is rapidly lost, even at refrigerator temperature if the serum is kept in a fluid form.

Antihuman hemolytic amboceptor is made by immunizing rabbits against human blood corpuscles. Large rabbits are injected with increasing amounts of washed human blood corpuscles five times in succession intraperitoneally, allowing a four-day or five-day interval between injections. Nine or ten days after the last injection the rabbit may be bled from the carotid artery, the blood collected in a tube and placed at room temperature for several hours before being transferred to the refrigerator. At the end of twenty-four hours the clear serum is collected by decantation and this should be titrated to determine its strength. Different rabbits react differently to amboceptor production and often a weak serum will be obtained after a long immunization, while at other times a powerful serum may be obtained after four injections. A good preparation will have a value of one unit in something less than 0.001 c.c. of serum; that is 0.001 c.c of serum or less will cause complete hemolysis of 1 c.c. of a 1 per cent. suspension of human erythrocytes when combined with an excess of complement, say 0.02 c.c. of fresh guinea-pig's serum.

Noguchi states that alcoholic extracts of certain tissues contain variable quantities of antigen for syphilis. There is more in heart, liver or kidney than in nervous tissues, so far as has been determined. The liver of a congenitally syphilitic fetus is one of the tissues richest in these antigenic lipoids. In the preparation of antigen the procedure is as follows:

> Extract a mashed paste of liver, heart or kidney of man, ox, guinea-pig, rabbit or dog with ten parts of absolute alcohol at 37 C. for several days. Filter through paper and collect the filtrate. Bring the latter to dryness by evaporation, and take up the residue with a small quantity of ether and add five volumes of acetone. A precipitate forms, which is allowed to settle to the bottom of the vessel and the supernatant fluid decanted off. This insoluble residue contains antigenic lipoids and its strength is estimated by taking 0.2 gram of the residue, dissolving it in about 5 c.c. of ether, and gradually adding 100 c.c. of physiologic salt solution to make an emulsion. If flocculent it may be filtered through paper to remove the precipitate. This opalescent emulsion is used for the fixation test to find out the quantity needed to cause complete inhibition of

hemolysis when combined with a good syphilitic serum. Inhibition is caused by the coexistence or simultaneous presence of antigen and syphilis-antibody, and is of diagnostic value. Any quantity of the emulsion which is capable of causing complete fixation may be used for the test, but it is best to choose the maximum dose which is without inherent anticomplementary action.

Noguchi says that his method if properly carried out gives uniform and reliable results; but as the activity of the complement and the resistance of the red corpuscles sometimes vary according to their source and age, certain irregularities sometimes arise, which necessitate a knowledge of how to adjust relatively the quantities of these factors. There are no difficulties that arise which cannot be removed by the proper use of the several reagents, and definite and detailed information concerning the manner of eliminating error is given. Whether the active, old or inactivated serum is used is only a matter of personal choice, provided that the rules prescribed for active and inactive serums are observed.

Concerning the value of the serum test for the diagnosis of syphilitic conditions, Williams[4] states that by combining the figures obtained from numerous investigators comprising over 8,000 tests, an average of 75 per cent. positive reactions were obtained in all cases of hereditary and acquired syphilis. He has tabulated the results, which are given in Table 1.

TABLE 1.—POSITIVE REACTIONS IN 8,000 CASES OF HEREDITARY AND ACQUIRED SYPHILIS (WILLIAMS)

Stage of Disease.	% Positive.
Primary syphilis.	70
Secondary syphilis	89
Tertiary syphilis	78
Early latent (late secondary symptoms)	51
Late latent (following tertiary symptoms)	47
Hereditary syphilis	95
Cerebrospinal syphilis	48
General paralysis	88
Tabes	63

Taking into consideration the fact that this includes tests made by various methods, some of which have been proved to be open to considerable error, it would seem that the value of the serum reaction has been thoroughly demonstrated.

Noguchi's method seems to be a distinct improvement over that of Wassermann or any of the other methods proposed for the reason that it is not so complicated and cumbersome; and the statistics seem to show that it is more accurate and more delicate. Thus, in a comparison of the Wassermann and Noguchi systems in 244 cases of syphilis and parasyphilitic conditions, as reported by Noguchi[3], the Wassermann system gave 183 and the Noguchi 211 positive reactions. Noguchi further states that in a series of 1,082 cases examined, in which there were a number of syphilis suspects, 802 positive reactions with the Noguchi test were obtained.

In a comparison of the Wassermann and Noguchi systems Fox[6] reports 210 cases examined with the percentages of positive reactions favorable to the Noguchi test. This series of cases included primary, secondary, tertiary, latent and hereditary syphilis, tabes, cases for diagnosis and non-syphilitic cases. In primary syphilis both the Wassermann and Noguchi tests showed 100 per cent. of positive reactions. In secondary syphilis the percentages of reactions were, Wassermann 97 per cent., Noguchi 100 per cent., in tertiary syphilis, Wassermann 71 per cent., Noguchi 84 per cent.; in latent syphilis, Wassermann 46 per cent., Noguchi 62 per cent.; in hereditary syphilis, Wassermann 100 per cent., Noguchi 100 per cent. (only one case reported); in tabes Wassermann 100 per cent., Noguchi 100 per cent. (three cases reported); cases for diagnosis, Wassermann 39 per cent., Noguchi 49 per cent. (53 cases reported). Of non-syphilitic cases, 2 cases out of 23 gave a positive reaction by Wassermann while 4 gave a positive reaction by the Noguchi test. One of these cases was afterward examined by Noguchi and gave a negative reaction.

In a similar series of cases reported by Kaplan,[7] out of 1,286 cases examined the positive reactions by the Wassermann test were 826 and by the Noguchi test 995.

Swift[8] in a carefully prepared article on "A Comparative Study of Serum Diagnosis in Syphilis," accompanied by numerous tables showing the number and kind of cases in which the serum diagnosis was tried, concludes that the Noguchi reaction is more readily applied and the materials are more easily procured and kept than with the Wassermann method. It is also more sensitive than the Wassermann reaction, though this increased sensitiveness sometimes causes a positive reaction with non-specific serums which gave a negative Wassermann reaction. Noguchi, however, states that these positive reactions with non-specific serum may be avoided by the use of inactive serum, and further that when one obtains a high percentage of positive reactions in non-syphilitic cases one should suspect that one is not doing the test properly.

Numerous investigators have attempted to determine the result of various forms of treatment on the syphilitic antibodies in the blood. It is known that the reaction frequently disappears after a short course of treatment, often to return again within a greater or lesser period of time. In some cases a positive reaction frequently persists in spite of treatment, and Noguchi states that in hereditary lues the reaction is difficult to get rid of, often persisting in spite of most vigorous interference. Frequent tests are necessary to determine whether further therapeusis is indicated. A positive reaction in a syphilitic case is an indication for additional treatment though it is not definitely established that the disappearance of the reaction is justification for the cessation of treatment.

It having been definitely established that by the serum test we are able to diagnose syphilis with more or less certainty, it is clearly evident that the test is going to prove of inestimable value to the ophthalmologist who constantly sees many cases of doubtful syphilitic origin. The method is used not only for the diagnosis of syphilis primarily but also as a guide to determine when treatment may be discontinued, or whether it should be resumed.

Up to the present time the reports do not show many eye cases in which the test has been used, though it is possible that some of the statistics in which the cases are grouped under the various types of syphilis may include some eye lesions. Noguchi reports only 29 cases of eye diseases in which his test was employed, and his table is here reproduced (see next page, Table 2).

In this series of cases it will be seen that nearly 50 per cent. of positive reactions were obtained. No reference is made to syphilitic history or the possible effect of treatment in causing a negative reaction in a case of syphilitic origin. Thus out of twelve cases of interstitial keratitis, which in a very large percentage of instances is of syphilitic origin, but eight positive reactions were secured. It would be interesting to know whether any of these negative reactions occurred in patients reasonably free from the possibility of syphilitic infection or whether treatment had anything to do with the results secured from the test.

TABLE 2.—CASES OF EYE DISEASES TESTED BY NOGUCHI BY HIS METHOD

	Cases Examined	+	—	±
Keratitis interstitialis	12	8	4	0
Iritis	6	4	2	0
Scleritis	1	0	1	0
Paralysis external rectus	1	0	1	0
Optic neuritis	1	1	0	0
Chorioiditis (exudative)	1	0	1	0
Optic atrophy	5	0	5	0
Acromegaly with ocular symptoms	2	1	1	0
Totals	29	14	15	0

From Dr. Swift's tables I have been able to select ten cases of eye diseases in which the data is more complete. They may be arranged as in Table 3.

An analysis of these cases shows only one negative reaction by the Noguchi test, which was also negative with the Wassermann test, and this case was one of ocular palsy accompanied by blindness, of questionable syphilitic history though the patient had had much antisyphilitic treatment for two years previous to the test. It is probable that the negative reaction in this case was due to the treatment, and that earlier in the history of the case the reaction would have been positive. In one case of iritis, with papular eruption, the initial lesion having been six months before the test, the Wassermann reaction was negative and the Noguchi reaction was decidedly positive. In the case of optic atrophy and blindness, in which syphilitic infection was denied, the Wassermann reaction was questionable, and the Noguchi reaction was weakly positive. Of particular interest are the four cases in which the history of infection is indefinite or infection is positively denied, and the lesion is doubtfully syphilitic from clinical symptoms and manifestations. In three of these cases the Noguchi reaction is positive and in the one that is negative the patient had much treatment for two years preceding the test. In all of the other cases there was a history of infection leading to the supposition that unless the patient had had much treatment the Noguchi reaction would be positive.

TABLE 3.—SWIFT'S CASES OF EYE DISEASES TESTED BY THE WASSERMANN AND NOGUCHI REACTIONS

Time Since Appearance of First Symptoms	Present Manifestations	Treatment	Wassermann	Noguchi
Four months.	Maculopapular; iritis.	6 weeks bichlorid pills.	+	+
Three months.	Papular; iritis.	Eighteen inunctions.	++	++
Five months.	Iritis.	Four months.	+	+
Two years.	Conjunctivitis.	Fair.	+	++
Six months.	Papular; iritis.	Poorly.	—	++
Three years.	Iritis.	None.	++	+
Denied.	Keratitis, myositis.	None.	+	+
Denied.	Optic atrophy; blindness.	Not stated.	+—	+
Indefinite.	Ocular palsy; blindness.	Much in past two years.	—	—
Denied.	Syphilitic iritis.	Little.	++	++

With a view to determining the clinical value of the serum test for syphilis in eye diseases and especially those of doubtful etiology I took up the work several months ago and in carrying it on I have had the cooperation of my assistant, Dr. Norma B. Elles, and of Dr. C. G. Beall, to whom I am indebted for valuable assistance. Owing to the difficulties encountered in satisfactorily carrying out the test and eliminating the commoner errors in technic bound to occur at first, it was only recently that our results have been considered in any sense reliable. It is frankly admitted that the absolute accuracy of the reported findings may be questioned on the ground that errors in technic are more likely to occur with those who are not specially skilled in hemolytic work, and who have not had the advantage of a long and varied experience. But in view of the scarcity of literature concerning the value of the tests in eye diseases I have thought our results in a limited number of cases worthy of report, though it is hoped that a subsequent report covering a very much larger number of cases, and reviewing the results secured by others, will throw still further light on what, it seems, must eventually be one of the most important diagnostic means at the hands of the ophthalmologist for diagnosing eye lesions of questionable syphilitic etiology.

In all of the tests, only a portion of which are reported, fresh guinea-pig serum was used as complement. The amboceptor, consisting of the serum from immunized rabbits, was obtained from the laboratory of the Memorial Institute for Infectious Diseases, Chicago, though in some of the tests amboceptor slips which originally came from Dr. Noguchi, of the Rockefeller Institute, were used. Our antigen, made from the alcoholic extract of the liver of a congenitally syphilitic fetus, was also obtained in the form of antigen slips which had been carefully standardized.

Unfortunately the first tests, consisting of a number of cases, proved worthless owing to a poor quality of antigen, as well as one which had not been carefully prepared and standardized. In consequence some of these cases were either lost sight of when we finally got the tests working satisfactorily, or treatment modified the result. The ear, nose and throat cases, which were also studied in connection with the eye cases, are not considered in this paper.

The cases, with condensed history and results of test recorded, are given in Table 4.

An analysis of these cases shows that of the thirteen positive reactions ten were in patients giving no definite history of syphilitic infection, and only two of the eight showed other than eye lesions to indicate syphilitic infection. Seven of the number had received antisyphilitic treatment and probably to the treatment may be attributed some of the weak positive reactions secured.

Of the thirteen negative reactions six were in patients who gave no history of syphilitic infection and received no antisyphilitic treatment. One patient (Case 12) denied infection but presented many evidences of secondary manifestations of the disease and was kept on mercurial inunctions for a period of two years previous to the test and constantly improved under the treatment. She gave a negative Noguchi reaction and no doubt the vigorous mercurial treatment and absence of active syphilitic lesions prevented a positive reaction. The same is true of Patient 26.

The four patients giving a history of syphilitic infection and treatment of the same probably gave negative Noguchi reactions because of the effect of the treatment. The lesions existing at the time of the tests were probably not syphilitic.

The patients suffering from or having suffered from interstitial keratitis would be expected to be syphilitic, and hence the Noguchi reaction in such cases would be positive except for the inhibiting influence of the treatment. The test in those cases, therefore, would be essentially valuable as indicating whether or not treatment should be discontinued or resumed.

TABLE 4.—AUTHOR'S CASES TESTED BY THE NOGUCHI METHOD

No.	Sex	Age	History of Infection	Manifestations	Treatment Before Test	Noguchi Reaction
1	F	34	Indefinite	Ectopia lentis. Opacities cornea due to old interstitial keratitis.	Some treatment for congenital syphilis.	—
2	F	14	Congenital	Interstitial keratitis. Numerous scars at corner of mouth and on face. Saddle-nose.	Much treatment for inherited syphilis.	—
3	F	20	Congenital	Old adhesions of the iris. Blepharitis. Interstitial keratitis.	Now taking antisyphilitic treatment. (Mercury.)	+
4	F	17	Congenital	Hutchinson teeth and other signs of congenital syphilis. Opacities of cornea. No active lesions.	Much antisyphilitic treatment.	—
5	M	13	Congenital	Granular conjunctivitis. Ulcer of the cornea.	Unknown.	—
6	F	21	Indefinite	Argyll-Robertson pupil and optic atrophy.	None.	+++
7	M	15	Indefinite	Scars of cornea. Adhesions iris. Nystagmus.	Questionable antisyphilitic treatment.	—
8	M	15	Questionable	Scars on cornea. Active phlyctenular conjunctivitis et iritis.	None.	++
9	F	14	Congenital	Saddle-nose. Scars corner of mouth. Interstitial keratitis 1 year ago.	Mercurials for several weeks 1 year ago.	++
10	F	26	Questionable	Neuroretinitis.	None.	++
11	M	40	Indefinite	Paralysis sixth nerve.	None (after a month's mercurial inunctions Noguchi reaction + ; after two months' treatment still +).	+++
12	F	29	Denied	Maculopapular eruption; ulceration of pharynx and nose, and iritis two years ago. Old adhesions iris. Active cornea[illegible]	Two years of active mercurial treatment (inunctions).	—
13	M	18	None	Hemorrhage into vitreous [illegible] endarteritis right eye [illegible] dust-like opacities in vitreous.	None (after a month's mercurial treatment and pilocarpin sweats Noguchi reaction +).	++
14	M	8	None	Interstitial keratitis one year ago. Ulceration tonsil and pharynx six months ago, smears from which showed *Spirochæta pallida*.	Mercury inunctions irregularly for one year. (After one month's continuous mercurial inunctions and injections Noguchi reaction +).	+++
15	F	60	None	Third nerve paralysis. Neuroretinitis.	Mixed treatment and pilocarpin sweats for a week.	+
16	M	38	None	Central leukoma. Active iritis.	None.	—
17	M	25	None	Iridocyclitis.	None.	—
18	F	24	None	Old adhesions and exudate closing pupil left eye. Active iritis right eye.	None.	—
19	F	64	None	Neuroretinitis and floating opacities in vitreous both eyes.	None.	—
20	M	31	None	Repeated hemorrhages in vitreous left eye for three years. Slight hemorrhages vitreous right eye. Obliterating endarteritis and hemorrhages in retina right eye.	K. I. irregularly for several months. Mercury for past few days.	+
21	F	35	Indefinite	Two attacks iritis in last six years. Mild attack iritis within last two weeks. History of two miscarriages.	Unknown.	+
22	F	47	None	Active episcleritis.	None.	—
23	F	31	Denied	Active ulceration nasal septum and iritis eight years ago. Return of ulceration two years ago. Iritis and interstitial keratitis now.	Active mercurial treatment for three years. Six months of mixed treatment two years ago.	+++
24	M	54	None	Repeated subconjunctival hemorrhages both eyes for past three years.	Unknown. Probably antisyphilitic from description.	+
25	F	52	*Indefinite*	*Aphasia* and one-sided sensory paralysis and partial motor paralysis. Few small spots of disseminated chorioiditis. History of one miscarriage.	Inunctions and large doses K. I. for six weeks. (Has recovered from aphasia and paralysis.)	—
26	F	50	*Negative*	Large syphilitic ulcer left tonsil, smears from which showed *Spirochæta pallida* nine months ago. *Old disseminated chorioiditis right eye.*	Almost continuous inunctions for eight months.	—

In the cases of iritis, except Case 23 (neuroretinitis, hemorrhages into the vitreous, and paralysis of eye muscles) there was no obtainable syphilitic history, no lesions other than those in the eye, and the cause was questionable. The serum reaction was considered satisfactory in determining the possibility of syphilitic etiology, and the results of subsequent treatment seem to establish the reliability of the findings. Thus in Case 11 the test was strongly positive and active antisyphilitic treatment not only produced marked improvement in the eye lesion but probably was responsible for a weakly positive reaction six weeks later. In Case 12, with unquestioned syphilitic lesions, and under active mercurial treatment for two years, the reaction was negative. This is considered an indication for cessation of treatment. Tests will be given later to determine whether treatment should be resumed. The active corneal ulcerations are considered as due to the effects of cicatricial changes in the lids, producing mechanical irritation, and the introduction of non-syphilitic infection. Case 14, with no active lesion, is considered as requiring more antisyphilitic treatment owing to the positive Noguchi reaction. Case 18 is one that ordinarily would be diagnosed as syphilitic iritis, but the Noguchi reaction was negative and the patient promptly recovered on treatment other than antisyphilitic.

Various writers have asserted that the reaction frequently disappears after a short course of treatment, often to return again within a greater or lesser period of time. This would seem to be borne out by the results secured in the cases reported by Noguchi, Brück, Citron, Swift and others. In our cases treatment very evidently tended to cause a disappearance of the reaction, and those patients who had received considerable antisyphilitic treatment and exhibited no active lesions at the time of the test, showed a negative reaction. Positive reactions were reduced to weakly positive following active mercurial treatment. Whether a positive reaction will be obtained in these cases later, after an interval of rest in treatment, will be determined later. Noguchi says that in hereditary lues the reaction is difficult to get rid of, often persisting in spite of the most vigorous interference. In several of our cases of congenital syphilis we secured a negative reaction which was thought to be due to the inhibitory action of treatment. Noguchi also says that the reaction may return shortly after cessation of treatment, so that it may be necessary to make frequent tests to determine whether further therapeusis is indicated. But he admits that it is not definitely established that the disappearance of the reaction justifies stopping treatment, especially as the reaction may be quickly affected by treatment.

In conclusion it may be said that the reaction is destined to be of value to the ophthalmologist as an aid in making a diagnosis, particularly in cases of doubtful origin, and also as a guide to selection of therapeutic measures. But to be reliable and hence of most value the test should be applied to those cases of which a reasonable complete history has been obtained; the reagents employed should be prepared in an accurate and careful manner: the technic as advocated by Noguchi and others should be accurately followed; and the interpretation of the results considered in the light of the experience and skill with which the tests have been made. The reactions should be verified, and control tests should be introduced as often as possible. Furthermore, all things being equal, the results will be most reliable and hence most valuable when done by those with facilities and training for hemolytic work.

ABSTRACT OF DISCUSSION

Dr. E. V. L. Brown, Chicago: One recent article in regard to this reaction might be quoted, namely, that of Alfred Leber, of Berlin, which covers some 300 cases of the Wassermann reaction. Many of the data coïncide with those of Dr. Bulson: for instance, 231 cases of eye diseases suspicious of syphilis gave a positive reaction in 40 per cent.; 71 cases of certain syphilis gave 79 per cent. of positive reactions; 22 cases of eye disease with metasyphilitic diseases, tabes, general paralysis and lues cerebri gave 82 per cent. of positive reactions. In 90 per cent. of 59 cases of hereditary eye lues there was a positive reaction. There were 82 cases of keratitis parenchymatosa, and of these 74 per cent. were positive. These included 63 per cent. of acquired and 11 per cent. of hereditary syphilis. In general, Leber states that the reaction is negative in 10 to 20 per cent. of syphilitic patients who have not been treated, and in 30 or 40 per cent. of those who have been treated. This very definitely restricts the application of the test. Leber has devised a complement deviation reaction for tuberculosis similar to the Wassermann reaction for syphilis. The technic is even more difficult than the Wassermann.

Dr. Albert E. Bulson, Jr., Fort Wayne, Ind.: The statistics quoted by Dr. Brown apply to the Wassermann reaction, while my paper is a consideration of the Noguchi reaction. I have reported comparative studies of the two reactions by competent observers, and the statistics presented seem to show that the Noguchi reaction is more reliable. For instance, in 244 cases of syphilis and parasyphilitic conditions, as reported by Noguchi, the Wassermann gave 183 and the Noguchi 211 positive reactions. In 1,082 patients examined by Noguchi, among whom there were a number of syphilitic suspects, 802 gave positive reactions. In another comparison of 210 cases of various kinds, in which there were a number of nonsyphilitic cases and cases for diagnosis, the percentage of reactions was decidedly favorable to the Noguchi test. The Noguchi test, therefore, seems to be more accurate, and hence of much more value than the Wassermann test; but it must be remembered that the value of the Noguchi test depends in large measure on the virulency of the infection, the stage of the disease, the influence which anti-syphilitic treatment may have had in altering the reaction, the reliability of the materials employed and the care and skill with which they are used, and the manner of interpreting the results.

In the so-called attenuated forms of syphilitic manifestation the Noguchi reaction may be but faintly positive, and the same may be true in the more virulent forms which have been actively treated with anti-syphilitic remedies. In either case the findings are significant as aiding in the diagnosis and indicating the line of treatment to be pursued. The reaction will prove of inestimable value in ophthalmic cases of doubtful etiology, particularly in certain fundus lesions, various ocular paralyses and the uveal disturbances, and in those cases of known syphilitic origin in which it is desired to determine whether antisyphilitic treatment should be resumed or not.

It seems to be proved that the Noguchi test is more delicate and less complicated to employ than the Wassermann, and probably more accurate. Its value, however, will be greater when carried out by one thoroughly familiar with hemolytic work and skilled in laboratory technic. Even then the interpretation of the results of the test will have greater value with added experience in its use. In my series of cases the results of the test, while subject to the possibility of some error, due to unfamiliarity with the work, seemed to point to definite conclusions, and the findings in most of the cases were either verified by the previous history, the character of the lesion, or the effect of the treatment. At a future session I hope to present the results of further study of the test in a much larger number of cases, as also to summarize the results of others who may be carrying on similar work.

THE RELATION OF ANIMAL EXPERIMENTATION TO OUR KNOWLEDGE OF PLAGUE *

GEORGE W. McCOY, M.D.
Passed Assistant Surgeon, U. S. Public Health and M.-H. Service
SAN FRANCISCO

Comparatively few diseases of man are readily transmitted to laboratory animals. In plague, however, we have an infection that can be reproduced in many of the animals ordinarily used for experimental purposes. The question then arises as to whether we know more about this disease than we do about infections that are less readily transmitted to animals, and those that thus far have not been studied in the lower animals. In reply it may be pointed out how much more accurate knowledge we have of the essential cause of plague epidemics than we have of outbreaks of typhoid fever, scarlet fever, measles, typhus fever and others that might be mentioned. When plague is to be combated, there need be no speculation as to the source of the infection. The outbreaking is not to be attributed to such vague and indefinite sources as impure air, a bad water supply, or a mysterious contagious influence; but we know that the problem is the simple and direct one of eliminating the infected rodent. Attention may be called to the fact that, fortified by our knowledge of this disease, much of which has been gained by animal experimentation, we are able to take such effective measures against its spread that, at the present day, plague in a community may be promptly controlled and even eradicated. In substantiation of this statement, the epidemics that have occurred at various times in the past few years in Oporto, Rio Janeiro, Glasgow, Liverpool and other cities abroad, and in San Francisco and Seattle in the United States may be cited. It is not too much to say that without the knowledge of the disease gained from animal experimentation these sanitary victories would not have been won. It is quite true that, even with this knowledge, little can be accomplished unless we have the intelligent assistance and cooperation of the community afflicted. In contrast to the splendid achievements in the cities mentioned we may cite countries where plague annually claims an enormous toll of human life; for example, India, where fanaticism manifests itself in the form of a violent antagonism to the

---

* This paper is one of the series prepared for and reprinted by the Council on Defense of Medical Research of the American Medical Association for circulation among the public. Fourteen of these pamphlets are now ready, taking up the relations of animal experimentation to ethics, diagnosis, cancer, vaccination, the live stock industry, tuberculosis, typhoid, dysentery, plague, rabies, surgery, internal secretions, circulation of the blood, tropical diseases, etc.

sacrificing of lower animals for any purpose, even such a laudable one as the suppression of a disease that on several occasions has claimed over one million victims per year. In China, there is no such antipathy to the taking of life of the lower animals, but there is found an ignorance and apathy most effective in nullifying any efforts looking to an improvement of sanitary conditions and surroundings.

Our knowledge of the cause of plague dates from the work of Yersin[1] and of Kitasato[2] in Hong Kong. These investigators, working independently, discovered the micro-organism that has since come to be universally recognized as the cause of the disease. They isolated the organism from the sick and from the bodies of persons who had died of the disease. The opportunity of reproducing the infection in laboratory animals was requisite to complete the chain of evidence necessary to establish the relation of the germ to the disease.

Prior to the work of the investigators mentioned, epidemics of plague were attributed to telluric and climatic conditions, to soil infection and to other sources. As a result of these erroneous views, intelligent measures looking to the suppression of the disease were impossible. The vigorous quarantines that were inaugurated, by reason of the hardship they inflicted, defeated the very purpose for which they were established.

Since the discovery of the actual causative agent of the disease, *Bacillus pestis,* progress in solving many of the problems has been rapid, and it may be asserted without fear of contradiction that every material advance has been made possible by the facts demonstrated by means of animal experiments. The subject will be considered first in the more important aspect, namely, the infected rodent, by means of which the disease is transferred from place to place and is spread in communities; and second, in relation to the preventing of the infection of individuals and in curing the sick.

RELATION OF RODENTS TO PLAGUE

Prior to the discovery of the organism causing the disease, the association of rat epizootics with outbreaks of human plague had been noted by several observers. That the oft-cited biblical verses,[3] which mention "emerods" and "mice," really referred to the association of plague and rats cannot be demonstrated; and the other early records are also the subject of much difference of opinion. The actual relation between the disease in rodents and that in man, however, had never been established. It was most important to prove this point, and to discover the actual manner in which the disease was spread among the rodents, and if possible, the manner in which man was infected from rodents. To these problems several investigators turned their attention. It is needless to point out that these questions could not be settled without recourse to animal experiments.

The earlier workers had found the plague bacillus in the bodies of insects that had fed on the blood of animals sick of the disease but it remained for Simond[4] to actually convey plague from one animal to another by means of insects (fleas). Simond found that when fleas were placed on a plague-infected rat they drew blood containing the plague bacillus, and that by transferring these infected fleas to a healthy rat the disease could be transmitted. Subsequently certain observers failed to confirm this work, but as is so often demonstrated, one properly controlled positive result is of more value than many negative ones. Simond's work was confirmed by Verjbitski[5] who succeeded in transferring the infection from rodent to rodent by means of fleas and other insects. Verjbitski's results were verified for the most part by the investigators of the Advisory Committee appointed by the Secretary of State for India, the Royal Society and the Lister Institute.[6] By means of an extensive series of experiments these observers found that plague infection would not spread among rats except in the presence of fleas. The same fact was found to hold good in the case of guinea-pigs. In other words, it was found that healthy rats and healthy guinea-pigs might be kept in close contact with plague-sick rodents, but that the disease was never transmitted to the well ones unless fleas were present. While this evidence was of great value in throwing light on the probable mode of transmission of the disease from rodents to man, or possibly from man to man, it was desirable to conduct experiments with animals more closely related to human beings, and for this purpose monkeys were used.[7] The monkeys were placed in cages in such a way as to simulate so far as possible the conditions under which man might be brought in relation to fleas from infected rodents. It was found that it was possible in this manner to convey plague to the monkeys.

Other most instructive and interesting experiments were performed by placing guinea-pigs in houses where plague cases had occurred, or where plague rats had been found. Many such houses were found to be infected as was shown by the fact that the guinea-pigs died of plague, and plague-infected fleas were found on them. In addition to these animal experiments, epidemiologic observations were carried out which together with the laboratory observations go far towards showing that, at least in India, the great majority of cases of plague are due to infection of man from rats through rat fleas.

Part of the work of this committee has been repeated by Kitasato[8] who reaches the conclusion that in Japan in the majority of cases the infection is conveyed in the same way as in India.

It may be thought that the presence of an epidemic among rodents under natural conditions would be manifested by so large a mortality among these animals as at once to make manifest the presence of the disease. Such, however, is not the case; it is exceptional to find a death-rate among the rodents large enough to attract the attention of the casual observer. With the exact knowledge of the mode of the conveyance of the infection and its relation to rats, the lines along which work must be performed to control an epidemic become well defined.

The demonstration of the relation of the disease in man to that in the rat, and the mode of conveyance from the latter to the former, explain many of the facts long known about plague epidemics such as the lack of contagiousness, the gradual, almost mysterious, spread through a community and through a country.

The measures for the control of a plague epidemic do not come within the scope of this paper, but we may state that they are essentially the ridding of a community of infected rats. We may be pardoned for emphasizing here what has been so often pointed out, that plague is not a "filth disease" in the ordinary sense of the term. Plague in human beings is definitely associated with the same disease in rodents, and ordinary sanitary measures have comparatively little influence on its spread. It can be controlled and prevented only by measures directed to the actual cause, the infected rodents.

What has been said thus far refers particularly to the bubonic type of plague, which is by far the most common in all epidemics and in all countries. The pneumonic type of the infection is also very important, especially for the reason that it is directly contagious from person to person, and has claimed many physicians and nurses for its victims. This type of the disease was described by the German plague commission[9] and by Childe[10] and its origin traced to the same micro-organism that is responsible for the more common bubonic type. It would have been impossible to prove that the pneumonic form of the disease was due to the plague bacillus but for the valuable assistance rendered by the methods of animal inoculation. Only less important than the relation of rat plague to human plague is the relation of plague in ground-squirrels to the same disease in man. This is especially true in America, for it is established beyond question that cases of plague in human beings have been derived from ground-squirrel infection.[11] It would have been impossible to prove the presence of plague among ground-squirrels on the Pacific Coast without resorting to animal experiments. Who would have accepted the diagnosis of squirrel plague had it been based on morphologic and cultural studies alone? Certainly no trained observer and probably no intelligent layman. It has often been found that the demonstration of plague in laboratory animals carries to the mind of the layman a conviction that nothing else will.

In most countries and in most communities the announcement of the presence of plague is a signal for a violent denunciation of those who have discovered or announced the presence of the disease; and if one were compelled to rely on methods of investigation other than the inoculation of animals it is probable that skeptics would never be convinced. It is most gratifying, and an evidence of the rapid progress in sanitary matters, that since the first announcement of plague among ground squirrels on the Pacific coast[12] no voice has been raised to question the diagnosis.

Two methods of inoculating laboratory animals with plague are in common use. The one is by the use of the ordinary hypodermic syringe; the second, usually known as "vaccination" or Kolle's method, requires simply the shaving of the skin and the rubbing of the suspected tissue or culture on the shaven area. Neither method is painful.

Now as to the use of laboratory animals in establishing the diagnosis of plague in persons or in rodents: In the majority of cases of plague a probable diagnosis can usually be made by clinical and microscopic methods; but in other cases it is necessary to resort to animal inoculations. Especially in the case of plague in rodents, resort to animal tests frequently becomes indispensable, as the tissues are apt to be invaded by other micro-organisms which speedily outgrow the plague bacillus so that methods other than the inoculation of animals are likely to fail. It is obvious that in order that measures looking to the protection of persons may be taken, a positive diagnosis is essential.

Animal experimentation is the only means at our disposal for determining the species that are susceptible to the disease, and thus learning which animals must be regarded with suspicion and which may be eliminated from consideration as possible agents in spreading the disease. This may be illustrated by two examples:

The first relates to the gopher; a very common rodent. When the squirrel-plague campaign was begun on the Pacific coast, the question arose as to whether it was necessary to destroy gophers as well as ground-squirrels. As a result of certain experiments that had previously been made with gophers at the Plague Laboratory, it was proved that the susceptibility of these rodents was so slight as to make it unlikely that any measures would need to be taken against them. Thus the lives of many of the little animals were spared without in any way lessening the value of the work from a sanitary point of view. It is only fair to say that farmers probably would have been much better satisfied had we not intervened in behalf of the little nuisances that are so destructive to certain crops.

Another field of usefulness of animal experimentation in relation to plague is illustrated by the following: In 1903, Simpson, a well-known student of the disease, made the assertion that the domestic animals and fowls found in Hong Kong, the meat of which was used for food, were susceptible to plague infection, and in his opinion constituted a possible source of danger. The determination of the facts in the case was obviously a matter of the greatest importance, and other workers took up the subject with the result that Simpson's findings were discredited[13] and a source of confusion and error was eliminated. It would have been out of the question to disprove definitely the erroneous statements without recourse to animal experiments.

Another field of usefulness of animal investigation in relation to plague is the search for a biologic agent that will cause an epizootic among rodents that will exterminate these pests but will not harm human beings or useful domestic animals. Unfortunately, up to the present time nothing fulfilling the requirements has been found. The usefulness of such agents can be determined only by conducting feeding experiments with rats and other rodents. The layman is very likely to be misled by the glowing advertisements of the biologic products that are on the market, and if they are used on a large scale with unfavorable results, a false sense of security is engendered and money is wasted that could have been spent profitably in other ways.

In the consideration of the relation of animal experimentation to the plague question, one must never lose sight of the fact that large numbers of rodents suffer from the disease in nature, and it is certainly no exaggeration to say that for each rat, guinea-pig or squirrel that has succumbed to the disease as a result of experimental inoculations, thousands of rodents have died of the same disease under natural conditions. The animal infected in the laboratory dies in peace and perhaps has his sufferings cut short by the merciful use of an anesthetic, while his brother infected in the ordinary course of events in nature is very apt to have his sufferings cut short only by the less merciful attentions of his cannibalistic comrades.

To follow to a logical conclusion the doctrine that animals should not suffer for the benefit of mankind would effectually put an end to the warfare against rodents; not only that conducted as a measure against disease, but as well that conducted by almost everyone on purely economic grounds. Traps and poisons are not merciful in their effects, and those who deplore the sacrifice of animal life made necessary by the advance of science would probably not hesitate to take measures looking to the destruction of the rat that has the pantry or the granary for the field of his activities.

PROPHYLAXIS AND TREATMENT

The matter of prophylactic measures that may be used to prevent plague infection or reduce the liability to it are clearly of great importance. The question of artificial immunization to plague is a subject that has received the attention of a number of observers. Haffkine's work along this line has given us a valuable weapon in the combating of plague. He injects killed cultures of the plague bacillus into persons with the object of creating a degree of immunity to the disease that would enable one to resist the invasion of the infecting organism. The method has been widely used in India and less extensively elsewhere. There is some difference of opinion as to the value of the procedure, but there is a very general agreement that no harm is done when the prophylactic is used with proper care. An unfortunate accident which occurred in connection with the use of Haffkine's prophylactic has materially interfered with its wider use. This accident was the infection of a number of persons with tetanus at the time of inoculation. The matter was made the subject of a rigid investigation and the evidence indicated that the tetanus was due to the accidental contamination of a vial of the prophylactic while the latter was being prepared for use by a native assistant. Even had the accident been due to the improper preparation of the agent it simply would have pointed out the necessity for the utmost care in the manufacture of the prophylactic.

Haffkine and Bannerman[14] in reviewing the work with Haffkine's prophylactic show clearly that there is a much reduced case incidence among the inoculated, and a startling reduction in the mortality of those in whom inoculation has failed to prevent infection. A particularly striking series of cases reported by Haffkine[15] is that of a large series of numbered prisoners who were confined in a jail where plague prevailed. Those who bore even numbers were inoculated, while those having odd numbers were not inoculated. Among the uninoculated there occurred ten cases of plague, six of which were fatal; while among the inoculated there were three cases, all very mild and all of the patients recovered. Other series of almost equally striking cases might be cited. Forsyth,[16] in an analysis of the figures of many thousands of cases, shows that the plague incidence among the inoculated was less than one-third of that among the uninoculated, while the mortality among those who had received the prophylactic was only 17 per cent.; and among those who had had no previous treatment it was 45 per cent. In other words, the chances of dying of plague were about eight times as great for those who had not received the prophylactic treatment. Numerous other reports of the same tenor might be adduced to demonstrate the value of the measure.

Strong[17] advocates the use of living but attenuated cultures of the plague bacillus for the purpose of immunizing persons. This method has not been largely used, but the evidence that exists is in favor of the procedure.

The whole subject of artificial immunization has been developed in relation to plague as well as in relation to other diseases by means of experiments on lower animals, especially rats and guinea-pigs.

Now let us state very briefly what animal experimentation has enabled us to do for the person actually stricken with the disease. In 1895 Yersin, Calmette and Borrel[18] found that after animals were injected with killed cultures of the plague bacillus, the serum of the animals so treated acquired the power of preventing the development of plague in animals that were simultaneously infected, and in curing animals already sick. The serum for this purpose is now on the market as an article of commerce. It has been used in thousands of cases of the disease in all parts of the world. There is a general agreement of opinion that when administered in sufficient doses and sufficiently early in the disease, it constitutes a very efficient remedy. Unfortunately the cases are rarely diagnosed early enough to give the patient the full benefit of the serum. Chocksy[19] says:

> "Much depends on the early and free use of the serum. In patients injected on the first day or within a few hours of the onset of the symptoms one injection of 100 c.c. followed by another after six to eight hours and then if necessary by a third, after a similar interval would cut short the attack if the case be not pneumonic, malignant or septicemic."

There is very good reason for believing that with the exception of the use of the serum, treatment has scarcely any influence on the course of the infection.

Laboratory animals must be used in the preparation and the testing of prophylactics and the curative serum. No other method is available, and to prohibit animal experimentation would immediately and effectually stop all work and all progress along these lines as well as along other lines of investigation of plague.

CONCLUSION

To review briefly, we may say that in the past by means of animal experimentation there has been demonstrated the cause of plague, the means by which it is conveyed in nature from animal to animal, and from lower animals to man. At the present time we have effective means of controlling outbreaks of the disease, and of curing many of the sick. So much has been accomplished in the past that we may fairly hope that later investigations will still further extend our knowledge of the disease.

If I might be permitted to suggest the lines along which we may expect progress they would be as follows:

1. The discovery of methods of rodent extermination more perfect than those we now have.
2. The development of a prophylactic agent that could be used without inconvenience on a large mass of the population.
3. The preparation of a curative serum, potent enough to make it useful even in late cases of the disease.
4. The discovery of a reliable method of early diagnosis of human cases without awaiting the results of culture and inoculation experiments. This will probably be in the nature of a test similar to the ocular reaction in typhoid fever or the cutaneous reaction in tuberculosis.

5. The circumstances governing the alterations of virulence of the bacillus.

All progress in the directions indicated will have to come about as a result of experimental work done on lower animals. Will any reasonable person say that this work must be stopped because it requires the sacrifice of even a large number of rodents? Shall the achievements of the past, splendid though they are, be the measure of what we shall know about this disease that claims so many victims and causes such enormous commercial losses? I believe that these questions may be left safely to the judgment of any unbiased person.

THE FILTERING CICATRIX FOR CHRONIC GLAUCOMA

WITH A REPORT OF CASES IN WHICH OPERATION WAS PERFORMED BY THE METHOD OF LAGRANGE *

ALLEN GREENWOOD, M.D.
BOSTON

Ever since the general acceptance of von Graefe's classical operation of iridectomy as the best operative treatment in the majority of cases of glaucoma, ophthalmic surgeons have observed that, in cases of chronic glaucoma, a more permanent benefit was often obtained in those in which, through some fault in technic, a cystoid scar resulted. Such a scar usually came about as the result of some entanglement or prolapse of shreds or tags of iris, with evidences that the anterior chamber communicated with the cystoid cavities by fistulous tracts. This observation led to deliberate attempts to produce such scars, and some operators advised leaving a bit of iris tissue somewhere in the wound for this purpose. Others, like de Wecker, Priestly-Smith and Critchett, while acknowledging the possible benefits, pointed out the dangers of infection and sympathetic disturbance from this procedure. In spite of this warning, several operators have recently advocated this method of making fistulous cystoid cicatrices, the most radical being Maher,[1] who, after making the usual incision, drags a section of the underlying iris from its attachment and leaves the loop prolapsed, to be cut off several days later, in such a manner as to leave a tag of iris in either corner of the wound. To lessen the danger in such cases, Herbert[2] advised covering the prolapse with a conjunctival flap made at the time of the incision. Holth[3] also tries to minimize the dangers by his new operation called "iridencleisis antiglaucomatosa," which he describes at length with its various incisions and modifications of iris treatment. The modification which he esteems the highest, and which he considers gives the best results, is that of subconjunctival incarceration of iris tissue combined with extrasphincteric iridectomy. He reports some excellent results and clearly establishes the possibility of creating a fistulous passage between the anterior chamber and the subconjunctival spaces with a reasonable amount of certainty. Holth's operation is far safer than Maher's and a step forward, but it remained for Lagrange to work out the possibility of obtaining filtering or fistulous scars free from iris tissue.

Ophthalmic surgeons, who have been accustomed, in operating for cataract, to make their incisions far enough back to get a good conjunctival flap, had noticed that the flap often remained edematous or even bleb like for some time after healing had taken place, and in a few cases, for years after, with the added observation that pressure on the eye would increase the edema or bleb with a decrease in tension and a partial emptying of the anterior chamber. Herbert especially called attention to this, and the explanation is found when one reads McKechnie's[4] most excellent article on the healing of variously placed cataract incisions.

Lagrange[5] reasoned that if this occasional undesirable sequel of flap extraction, with its fistulous communication between the anterior chamber and subconjunctival space, could be brought about in all cases of iridectomy for chronic glaucoma, the likelihood of future increases of tension would be greatly lessened, and the cure produced by the iridectomy made more permanent. The description of the operation which he therefore devised and called sclerecto-iridectomy, with the very excellent cuts, has been repeated so often that it is unnecessary to give a full description here.

Briefly, it consists in a sclerocorneal incision well into the angle of the anterior chamber, with the knife held, in cutting out, with the edge slightly backward so as to bevel the sclera and make a broad conjunctival flap. Then with the conjunctival flap pulled down over the cornea, a portion of the beveled edge of the sclera is cut off with curved scissors, the amount varying with the degree of plus tension, as experience shows that the greater the tension the less the amount necessary to remove. A good iridectomy is then made and the conjunctival flap replaced after all iris tissue has been freed from the angles of the incision. In regard to this latter point, Lagrange holds that his operation has not been properly performed if any entanglement of iris tags occurs. He reported some very encouraging results. I have performed the Lagrange operation now nine times and have not found it especially difficult or very disturbing to the eye, the amount of traumatism being less than one would expect. I find the curved modification of de Wecker's iris scissors the best to cut the beveled sclera.

Herbert,[6] in describing his wedge isolation operation, says:

> The term filtering should be restricted to smooth, even scars, which evidently allow aqueous to pass through them, but which present no dark points which we can accept as fistulous openings. The fact of filtration is shown by the edematous condition of the overlying conjunctiva, and particularly by the fact that pressure on the eye causes a marked increase of this edema, often amounting to a bleb and a marked lowering of the tension of the eye.

This operation I have never tried, as the operation of Lagrange appealed to me as being less complicated and more likely to give a permanent result. Herbert claims that his operation creates a true, filtering cicatrix, but that the operation of Lagrange creates a subconjunctival fistula. Granting that this statement be true, it still would seem to me that a tiny, subconjunctival fistula, or group of fistulas, would be more likely to remain permanent than microscopic filtering spaces in scleral scar tissue.

---

[7] Henderson: Ophthalmoscope, December, 1907.

Thomson Henderson,[7] in an article, written from the standpoint of a pathologist, on the so-called filtering cicatrix, described the processes of healing of corneal wounds, especially those made at the limbus, pointing out the fact that "after an incision into the anterior chamber, whatever its position, or method, or formation, the endothelial cells go along with internal margin of the wound and so come to seal it off. Once the growth of endothelium is complete, the wound is no more a filtering cicatrix, but is shut off from the anterior chamber by a layer of new-formed endothelial cells, which proceed to lay down a new homogeneous membrane between the cut surfaces of Descemet's membrane." It is this endothelium that precludes, according to Henderson, all possibility of a permanent filtering cicatrix following any operative incision, however devised. He says in concluding:

> I would emphasize the fact that the success of operation in glaucoma does not lie in a "filtering" wound but in the accompanying iridectomy. The reason of the beneficial and curative action of iridectomy in glaucoma is accounted for by the fact that the cut iris surface, forming the base and pillars of the coloboma, never undergoes any reparative process, but always remains a raw, open wound, as when first severed, so acting as a permanently open filtering area through which the aqueous fluid can drain away. The efficacy of this drainage area depends on the operation being done before atrophy of the iris stroma has progressed too far.

He seems to make out a very clear case against the permanence of the filtering scar as defined by Herbert, but does not disprove the possibility of the fistulization of an iris-free cicatrix. He does not explain away the observation of the several operators who have seen cicatrices, without macroscopic evidences of fistulization, that would allow the emptying of the aqueous into the subconjunctival spaces following pressure on the globe.

Abadie[8] has also expressed a pathologist's disbelief in the filtering cicatrix, asserting that in simple section of the iris must be sought the true remedial agent. He regards it as established that "(1) Lagrange has so far failed to furnish satisfactory proof that simple chronic glaucoma can be cured by sclerectomy; and (2) glaucoma cured by sclerectomy or by iridosclerectomy might equally well have been cured by iridectomy, a simpler and less dangerous operation."

Dr. Doyne[9] reported a favorable case done before the surgeons at the Oxford Congress by Lagrange, but does not mention the ultimate success as to filtration.

Dr. J. E. Weeks[10] presented four cases to the Section on Ophthalmology at New York Academy of Medicine, stating that the operation impressed him favorably.

Thompson[11] presents very clearly and concisely the gist of the controversy on the so-called filtering cicatrix. He says: "Nothing in ophthalmology could well be of greater importance than the [illegible] whether or not an iris-free filtering cicatrix can be made in the corneo-scleral margin, when operating for chronic glaucoma." He then goes on to describe the claims of Herbert and Lagrange, who, by their operations, are trying to establish a permanent path for the passage of aqueous from the anterior chamber into the subconjunctival tissue. He then gives Henderson's views as to the impossibility of making a permanent, iris-free, filtering scar, such as Herbert claims to obtain.

Lagrange[12] steps into the arena again, with a very able defense of his operation. In regard to the cystoid cicatrix, he makes the following very timely remarks: "A cystoid cicatrix, obtained at the price of an entanglement of the iris, is unwelcome and dangerous, and one should aim at creating a cicatrix fully as filtering as the cystoid one, without the uveal tract participating in its formation." He insists on going with the section through the ligamentum pectinatum iridis and dividing the insertion of the ciliary muscle, so as to establish a communication between the lymph spaces of the chorioid and the anterior chamber. He shows that von Graefe and de Wecker both understood the usefulness of the filtering cicatrix, but he gives to de Wecker the credit of having brought into prominence the value of this cicatrix. He also shows that de Wecker was opposed to the entanglement of iris in the efforts to obtain such a cicatrix. He goes on to describe the utility of the filtering cicatrix, and shows that "when it occasionally follows a simple iridectomy it is the result of the hypertension of the eye, and does not occur in chronic glaucoma without this hypertension." In such cases of glaucoma he states that iridectomy has no value, or but a passing one, because the lips of the wound fall into apposition, either immediately after the incision or more or less quickly after the section has been made. "Dieresis must be replaced by exeresis, since by the former it is impossible to produce a definite filtering cicatrix, which, on the contrary, one can get readily by exeresis of the sclerotic." He says:

> My operation of sclerecto-iridectomy has the primary advantage of opening up a communication between the choroidal space, on the one hand, and the aqueous chamber on the other. It satisfied, therefore, the wants of those who believe that chronic glaucoma largely depends on the obliteration of that space. In the second place, it does away with the obstruction of the angle of the anterior chamber, when such exists, and lastly, it establishes a communication between the aqueous chambers and the perichoroidal space and the meshes beneath the conjunctiva.

He describes three varieties of the filtering cicatrix based on the amount of sclera removed and the result of such removal. In the first variety there is the simple thinning of sclera; the second is the so-called subconjunctival fistula; and the third variety, in which there is ampulliform elevation of the conjunctiva added to the fistulization, resembles a cystoid cicatrix, but without the entanglement of iris. Lagrange states that since he began to operate on patients with a view of obtaining this form of the cicatrix he never has seen the least damage result from the operation.

Lagrange,[13] in a communication made to the Paris Ophthalmological Society, reports cases of simple sclerectomy giving successful results, which he considers more convincing proof of the value of the filtering cicatrix than cases of the combined operation, and especially is this true of the cases, like Valude's,[14] yielding good results where a previous simple iridectomy had failed. In concluding, Lagrange advises simple sclerectomy for cases having a tension of + 1 or less, reserving the combined operation for those having a greater tension. Later, Lagrange[15] answers M. Abadie's four objections to the operation of sclerecto-iridectomy, giving the clinical proofs in support of his claims.

Weekers and Heuvelmans[16] demonstrated, by experimentation on the eyes of rabbits, that it was possible to obtain a filtering cicatrix. They concluded from their experiments that it was necessary to excise a portion of

the whole thickness of the sclera, and as near the cornea as possible, in order to obtain a fistulous opening. They also state that it is necessary to do an iridectomy in most cases to prevent the inclusion of iris tissue in the opening.

Rochon Duvigneaud,[17] in discussing the Lagrange operation, and describing two cases, insists that the third variety of the Lagrange filtering cicatrix must be obtained if permanent reduction of tension is aimed at, that the simple thinning of the sclera obtained in the first variety is in no sense a filtering area, and that the improvement obtained in cases of chronic glaucoma, having such cicatrices, is due solely to the accompanying iridectomy. Apropos of the first variety of the Langrange cicatrix, Bettremieux[18] has endeavored to lessen the resistance of the sclera by grooving it near the cornea, without opening the anterior chamber.

Holth[19] describes a modification of the Lagrange operation, in which a modified Dr. Vacher punch forceps is used to remove the bit of scleral tissue. He tried taking the rounded piece of scleral tissue from the posterior lip of the wound, but finally decided to follow the method of Lagrange and take it from the anterior lip, using the punch forceps instead of the scissors.

Holth considers that the following three conditions must be fulfilled before an operation for the cure of glaucoma by the production of a fistulous cicatrix can be considered to have answered the purpose for which it was devised. He postpones publication of his results until sufficient time has elapsed to allow of their being fulfilled in a series of cases:

1. There must be conjunctival edema over and around the scleral wound, showing the presence of a subconjunctival fistula.
2. The tension must be constantly normal or subnormal, as shown by the tonometer.
3. For two years after the operation, the visual acuity and fields (which often improve to a marked extent) must not become worse than they were before.

Finally, Holth expresses his opinion that, although the classical iridectomy is still indicated in acute glaucoma, yet Lagrange's idea was a most happy one, and that anterior subconjunctival sclerectomy is destined to be the basis of all the future surgical treatment of chronic glaucoma.

Major Elliott[20] concedes that Herbert and Lagrange have proved their case, but considers that "the operation of Herbert is a difficult and complicated procedure, and that the operation of Lagrange, while less difficult, offers some risks," while the operation he advocates can be easily performed, and without the same risk. Briefly, his operation consists in trephining at the limbus with a 2-mm. trephine, leaving the button in place, or removing it with the trephine or scissors and forceps. In most of his cases the button was removed, and in some, twenty-one out of fifty, a small button of iris was removed. Fifty patients were operated on, and in no case up to the time of publication had the operation failed to relieve tension.

In another article[20] Major Elliott reports four cases showing the evidences of a filtering cicatrix a long time after operation; the first, eighty-six days; the second, three and one-half years; the third, seven and one-half years; and the fourth, ten years. The last two of these appeared to owe their filtration to tiny fistulization. His communication, he states, is simply a preliminary note on a new operative procedure for the establishment of a filtering cicatrix in the treatment of glaucoma. At the December meeting of the New England Ophthalmological Society, Dr. Verhoeff[21] presented a circular punch based on the principle of the bicycle tire punch, which will remove a button of sclera at one or both ends of a sclerocorneal incision, with a minimum of traumatism. He first cuts a conjunctival flap, which is pulled down over the cornea, and a sclerocorneal incision is then made with a keratome. The little rounded guard of the punch is then slipped into the wound, and to one corner, when by screwing down the sharp-edged cylinder, the button is cut and removed with the instrument. A small extrasphincteric iridectomy is then made. Fergus[22] also recommends a similar modification of Lagrange's operation by using the trephine, which is applied far enough back to avoid opening the anterior chamber, to which he adds a modified cyclodialysis obtained by pushing a repositor between the exposed ciliary body and the sclera, until its point comes into the anterior chamber. He has, therefore, modified the operation of Heine rather than that of Lagrange. Stephenson[23] reviews the use of the trephine in the treatment of glaucoma, calling attention to its advocacy by Argyll-Robertson thirty-four years ago, and later by Blanco and Frölich. These operators removed the scleral piece posterior to the ciliary body, while Fergus, Elliott and Verhoeff, now remove the disc from a point nearer to the limbus.

In 1905, Heine brought out his operation of cyclodialysis for the establishment of a passage for the escape of aqueous from the anterior chamber into the suprachorioidal space, and in the discussion of the question of a filtering cicatrix it would seem proper to bring up the question of this operation, which, however, could hardly be compared with the true filtering cicatrix, in that the passage of aqueous into the suprachorioidal space, following cyclodialysis, has been proved to be only temporary. The operation, however, is of value in certain classes of cases in which a sudden emptying, or partial emptying, of the anterior chamber is unwise. In such cases, Heine's operation should not constitute the whole treatment, but should be employed preliminary to a Lagrange, or some of its modifications. It is especially indicated in cases in which there is a high degree of tension with a marked sclerosis of the retinal arteries and consequent danger of hemorrhage, and particularly in those cases in which the fellow eye has been lost by reason of such an accident. Weekers[24] reports on five cases, in which Axenfeld operated after Heine's method, and which gave disappointing results in that the tension fell only to rise again. The operation devised by Fergus may prove to be a modification of the Heine, with the advantage of more permanent results. Fuchs has tried trephining, but operating away from the cornea, and only found that temporary relief was obtained. He has also tried Heine's operation, but has given it up as it did not permanently cure the condition, and as on pathologic examination it was shown that in cases in which cyclodialysis had been performed cicatrization completely occluded the spaces between the anterior chamber and the perichorioidal space. Arnold Knapp[25] reports a number of favorable results following the use of Heine's operation in his hands, but the gen-

eral opinion of surgeons who have tried the operation seems to be that it is not permanent enough in its effects to generally replace iridectomy for chronic glaucoma, while the Lagrange operation, or some of its modifications, seems to be growing in favor.

Case 1.—*History.*—The patient, F. M., aged 23, watchmaker, came to me Sept. 13, 1907. The case is especially interesting on account of the youth of the patient. The family history is also interesting in that the mother, at the age of 46, came to me with absolute glaucoma of the right eye, which, not yielding to iridectomy twice performed, required removal. Outside of glaucoma in the mother, there is no other family history of importance in the case. For three months before the patient came to me, the sight of the right eye had gradually failed with occasional attacks of discomfort, and the constant appearance of a rainbow around lights. On waking up in the morning both eyes were slightly congested, but this passed off in a very few hours.

Examination.—This showed the right eye vision equal to perception of light and perception of movements in the temporal field only. Tension + 1, and the pupil slightly dilated with anterior chamber shallow. The fundus showed a cupping of the disc amounting to three diopters with the retinal arteries pulsating. The left eye showed a vision of 20/30, field of vision normal, pupil slightly dilated and anterior chamber slightly shallowed, tension possibly slightly above normal, but difficult to determine owing to inability to compare with the normal eye. The fundus showed a cupping of about two diopters. Arterial pulsation only on pressure. In both eyes the optic discs were unusually large with the cupping sharply at the edge of the disc and sclera, with the vessels disappearing momentarily, entirely, in both eyes. The right eye showed entire loss of the nasal field up to the middle line.

Pilocarpin was immediately ordered and arrangements made for the patient's admission to a hospital for operation. The pilocarpin reduced the tension in the right eye, and contracted the pupils well, improving the vision in the right eye to counting fingers at two feet, in the temporal field, and improving the left eye to a vision of 20/30.

Operation.—On September 18 a Lagrange operation was performed on the right eye, and as this was the more advanced as to the glaucoma, only a small portion of the beveled edge of the sclera was removed. A moderate-sized iridectomy was performed and the large, well-shaped conjunctival flap was easily replaced. I was surprised at the ease with which the conjunctival flap could be pulled down over the cornea, out of the way, allowing an iridectomy to be performed as easily as after a keratome incision. A week later the same operation was performed on the left eye, and a large-sized piece of sclera removed. In this eye I also obtained a very good iridectomy and reposition of the conjunctival flap.

Postoperative History.—The healing was uneventful and unaccompanied by any entanglement of the iris in the wound. The edematous condition of the conjunctival flap was, of course, very marked, especially in the left eye. This condition of localized edema, which could be increased on manipulation of the eye, persisted for several months, and was present when the patient was seen Jan. 20, 1908, at which time the left eye showed a vision of 20/20, with a —2 cyl., axis 90°. The right eye could count fingers at two feet, in the temporal field, and in both eyes the tension was normal or even subnormal. The patient had returned to his work at the watchmaker's bench. I saw him again March 1, 1910, more than two years after my last record, and found the following conditions: The right eye, which looked perfectly white and quiet, still retained the same amount of vision, and had a normal tension. The line of incision showed very plainly as a bluish mark from 0.5 to 1 mm. in width, extending a little less than the length of the original incision. Just to the left of the center of this bluish line, there was a round bluish opening with a refracting center, as though a bubble of air were caught just under the conjunctiva. It had a diameter of 1 mm. and I felt that this represented a distinct fistulous opening into the anterior chamber. There was no surface elevation of tissue over this spot, but the conjunctival tissue represented by the original flap was slightly and evenly edematous, with a slight increase of this condition following pressure on the lower part of the eye. Continued pressure, however, did not create anything like a bleb or visibly decrease the fluid in the anterior chamber. The left eye showed, with his glass, a vision of 20/15. The eye was perfectly white and quiet with normal tension and no sign of conjunctival edema, and the incision showing as a bluish line, rather wider than that in the right eye, but having no appearance of fistulization.

In this case it is evident that the glaucomatous condition has been entirely relieved, though it is questionable if there is any filtration, at present, through the cicatrix of the left eye. It seems justifiable to suppose, however, that the marked filtration which was present for more than three months after operation allowed a more permanent cure from the iridectomy. The right eye, however, shows, after over two years, most of the evidences required to prove the presence of an iris-free filtering or fistulous cicatrix. My previous experiences with miotics and simple iridectomies for such advanced cases as represented by this right eye would lead me to expect a steady decline in vision instead of the complete maintenance of a vision which this patient insists is of great help to him.

Case 2.—*History.*—The patient, Mrs. G. H., gave a negative family history. For several years the sight in her right eye had been gradually failing up to Dec. 15, 1907, when she was stricken with a very severe attack of capillary bronchitis, and on the following day developed an acute attack of glaucoma in this right eye.

Examination.—When I saw the patient, December 16, I found the right eye in condition of acute glaucoma, with entire loss of vision, steamy cornea, with greenish pupillary reflex; tension + 3, and eye very much inflamed with conjunctival chemosis and extreme pain. She was coughing incessantly, and in view of her condition it was considered inadvisable to operate. Physostigmin (eserin) was accordingly prescribed to be used every three hours, and under this the pain ceased, the pupil contracted to nearly normal size, the cornea became less steamy, and the patient could discern movement of the fingers at two or three feet.

Operation.—No further improvement in vision took place, however, and the patient's condition improving, a Lagrange operation was performed on both eyes Jan. 2, 1908. The performance of the operation was very difficult on the right eye owing to the shallowness of the anterior chamber and excessive hemorrhage. The operation on the left eye was performd with no difficulty, and semed advisable on account of the finding of slight cupping of the disc and shallowness of the anterior chamber, with a slightly larger pupil than one would expect in a woman of her age. There was, however, no increase of tension, but the eye was evidently in a condition to develop glaucoma easily. The healing was uneventful in both eyes, with appearance similar to those described in the first case. The right eye, however, at the end of three weeks developed some increased tension and pain, and there were no signs of escape of aqueous into the subconjunctival space. A second Lagrange operation was then performed to the temporal side of the original one.

Postoperative Condition.—This resulted in reduction of tension, which has remained up to the present time, though the eye has only perception of light, practically no increase of vision having been obtained from either operation. This patient was seen again March 1, 1910, over two years after the performance of the operations. The left eye showed perfectly quiet and white with no conjunctival edema, and good clean coloboma without entanglement of the iris in the wound, and the line of incision showing as a bluish-gray area, about 0.5 mm. wide, extending nearly the full length of the original incision. There was no sign, however, of fistulization, to the naked eye. The vision with a + 3.50 sph. combined with a + 1.12 cyl., axis 175°, is 20/20. The right eye showed a regular, continuous, bluish line along the site of both incisions, varying from a millimeter in width down to nothing. At the point where the two incisions came together, and also at the nasal end of the first incision, there was some entanglement of iris. There was no sign of conjunctival edema, but there was a small, bluish cystoid scar at the nasal side containing some iris tissue without other signs of a fistula. The tension was normal, and there was absolutely no pain or discomfort.

The other Lagrange operations which I have performed are so recent that I will not detail them, but simply state that all four, up to the present, show the conjunctival bleb indicative of aqueous escape into the subconjunctival spaces. They were all performed in cases of simple glaucoma in which no history or signs of previous acute or subacute attacks had ever been present, and in which the vision and fields were much reduced, and the discs cupped and atrophic; the results so far have been most encouraging as to improvement in a vision which had been steadily failing under the careful use of miotics. I should state here that in neither of my two reported cases, which now are over two years old, has any miotic been used since the Lagrange operation, nor has any been used since operation in the newer cases, so that all the improvement and maintenance of vision must be ascribed to the operation.

From my reading coupled with my personal observation, I feel reasonably sure that the Lagrange operation, or one of its modifications, has come to stay because it is a distinct advance in our operative treatment of chronic glaucoma, in that it makes the effect of an iridectomy more marked at first, and more permanent later, thus keeping the vision existing at the time of operation much longer than can be hoped for from miotics, simple iridectomy, sclerotomy or cyclodialysis.

101 Newbury Street.

ABSTRACT OF DISCUSSION

Dr. John E. Weeks, New York: From the reading of the first paper of La Grange, the proceeding that he described impressed me favorably and at the first opportunity I began performing the operation. I have operated after this method in glaucoma, I think, 37 times. The operation is an iridectomy made in the manner which is at the present time classical and, in addition, the excision of a small piece of sclera. The incision is made by means of a Graefe cataract knife, making a large conjunctival flap. The operation itself is not a difficult one, in my opinion. The incision can be made so obliquely that, by grasping the conjunctival flap and pulling it forward, the piece of sclera to be excised can be exposed and rapidly excised by means of the curved scissors. I have watched very carefully the results of this procedure, and I have been very favorably impressed by it. Only a short time since a patient came to my office on whom I had operated some three years ago, and I found in that case that there was an actual filtration cicatrix in each eye. I had operated on both eyes. I found that the conjunctiva over the site of the iridectomy was somewhat raised, edematous, and by pressing on the eye the edematous condition could be increased slightly. Such is not the case in all the patients on whom I have operated, by any means, but the various cicatrices as represented by La Grange have been observed in the cases in which I have operated. First, in some of them the surface was perfectly smooth and the incision was filled by a cicatrix which showed no irregularities; second, in others there was some irregularity in the cicatrix, but not any evidence of filtration; third, there were still others in which the evidence of filtration was perfectly clear and pronounced. I know that the observations of Henderson and his histologic experiments seem to negative the claims of La Grange. Henderson concludes that the scar fills so that it entirely blocks the incision, and that no filtration results. This is true, I think, in many of the cases, but not in all. We have, then, in this operation, an iridectomy which is usually as efficient as an iridectomy made in any other way, and in addition the formation of a cicatrix, which may be a filtrating cicatrix in some of the cases at least. Moreover, if the tension does recur it is very much later in the cases in which a simple iridectomy has been performed. While at one time my impression was that I should revert to the ordinary iridectomy, at present I am of the opinion that I shall continue to use the operation of La Grange.

Dr. H. Gifford, Omaha: I do not think that we need waste any time in discussing the possibility of making a filtrating cicatrix; that is to say, a cicatrix or opening that will stay open, between the anterior chamber and the subconjunctival tissue. I think all of you have seen, as I have, these blebs remain after an iridectomy performed in the various ways, or after cataract operations, and if you will begin massage after iridectomy and keep it up you will keep up such a bleb. But the question whether that will lower the tension of the eyeball permanently is a different one. In many cases in which I have seen this bleb left the tension has gone up, just as it has in other cases. In one case I had a beautiful bleb which stood up in bold relief in both eyes, but the poor man's tension kept up and the sight went down until he finally killed himself. So that it remains to be seen, and it will take a good deal of time for us to tell, whether anything is gained by this cutting out the sclera. Theoretically one would expect to find the shreds of connective tissue going across this opening and filling it up; but even if it does not the question of its effect on the tension is still, I say, an open one.

Dr. Allen Greenwood, Boston: Holth in his article says that no case is successful unless the tension has remained normal for two years and unless at the end of two years there remains evidences of a filtering scar. This result Holth has undoubtedly obtained, according to his written description of the cases in which he has operated, and I feel confident that, in the few cases I have seen, the tension has remained down better than after the ordinary iridectomy, particularly in the cases in which the tension before the operation was considerable; and it is in those cases, as La Grange has pointed out, that you get the best results. I do not mean in cases in which there has been any inflammatory disturbance of the eye. Most of my patients have had no inflammatory signs of glaucoma; simply a cupping of the disc, with slight increased tension or occasionally plus one or over. In regard to doing the operation, it is simply an addition to the ordinary iridectomy made with the flap incision, and the cutting off of the small bevel of the sclera adds practically little to the operation itself, and I think it is an operation that for certain cases has come to stay. I think that all of you will be doing it later.

I have thus in my paper presented as briefly as possible the different operations recently devised for making the effects of glaucoma operations more permanent by efforts to establish a filtering cicatrix, or what might be better termed a subconjunctival fistulization of the sclerocorneal scar. Since writing my paper I have done additional La Grange operations, so that in all fifteen eyes have been operated on with only the happiest results. The later operations show even more clearly earlier evidences of fistulization than did those done at first. In cases in which the iris follows the aqueous out of the incision the iridectomy is done first, and then the sclerotomy follows.

Eucalyptus Oil in Treatment of Hookworm Disease.—P. Wijn writes from Ngawi in Java that the number of patients with ankylostomiasis is constantly increasing in the island. During 1907 such patients formed 4 per cent. of all applying to the Policlinic, and the proportion is becoming larger yearly. But he has found a method of treatment which seems to act much quicker and more reliably than the male fern or thymol. He prescribes:

℞.	gm.	
Olei eucalypti	2|5	gr. xl
Chloroformi	3|5	gr. liv
Olei ricini	40|	℥iss

This is taken three times a week in two doses, with a two-hour interval, in the morning, fasting, with a dose of castor oil the day before. The patients are allowed to go home each day after their medicine has operated. A single course of the kind proved effectual in nearly every instance, and never more than two were required. His communication is published in Janus, March, 1910, xv, 178.

ANOMALOUS SCARLET FEVER

A REPORT OF THREE EPIDEMICS*

WILLIAM THOMAS CORLETT, M.D., L.R.C.P. LOND.
Professor of Dermatology and Syphilology, Western Reserve University

AND

HAROLD NEWTON COLE, PH.B., M.D.
Resident Physician, Lakeside Hospital
CLEVELAND

During the past decade there have occurred in Lakeside Hospital three epidemics of what is thought to be anomalous scarlet fever. In each of these epidemics the disease might have passed unrecognized or at least some doubt might have been entertained as to its nature, had not one or more typical cases occurred which acted as a diagnostic control. These epidemics were characterized by the mildness of the attack, the benign course of the disease together with the suppression or complete absence of the exanthem together with some other of the more important symptoms.

The first epidemic occurred in the winter of 1904-5 and started in the children's ward, but before strict quarantine and disinfection terminated its spread, the medical and surgical wards likewise contributed until eighteen cases were observed.

REPORTS OF CASES

CASE 1.—A child admitted with some slight ailment was observed to have a faint rash on the neck and face which soon disappeared, although a redness of the fauces persisted somewhat longer. There had been but a slight rise in temperature and the case attracted no special attention.

CASE 2.—A child aged 3 was admitted to the surgical service with tuberculosis of the knee. On November 30 the knee was aspirated and iodoform emulsion was injected. December 1 the temperature, which had been about normal, registered 103 F.; it became normal again on the 2d, and the following day again arose to 103. On the 4th a slight reddish, papular rash noticed over the trunk with flushing of the face. This was thought to be due to iodoform poisoning. Further examination, however, brought to light changes in the fauces; and the tonsils were red and slightly swollen. Three days later, December 7, the night nurse on duty in this ward came down with a typical infection of scarlet fever of moderate severity, whereon both were immediately isolated. The child ran a mild course with slight desquamation and was discharged Jan. 13, 1905.

CASE 3.—The case of the nurse above mentioned ran a typical course of moderate severity. It is noted that differential blood-count showed a marked increase in eosinophils.

CASE 4.—A child, aged 11 months, was in the surgical service for a hare-lip operation. Some time after the operation it was noticed that the temperature, which had been normal, suddenly arose to 103 but returned again to the normal two days later. Three days after this, December 4, it registered 101 and the next day the face was flushed, except around the mouth, and a slight rash could be made out over the body. There was also inflammation of the throat. The child was isolated, and three days later the rash had disappeared. The temperature at this time was 99. Desquamation had already begun around the neck. From this time the temperature became irregular and later a discharge was noticed from the left ear. The notes of the case show that the child was discharged well, Jan. 11, 1905.

CASE 5.—A hospital nurse, aged 19, complained of a headache, was chilly with a sore throat on December 4. On the afternoon of the same day the left tonsil was red and puffy with pin-point white spots. The temperature was 101.6. The next morning she still had headache and vomited once after taking magnesium sulphate. The tonsil being still "puffy and sore" the patient was taken to the operating-room to have it incised when one of us was asked to see the case. A diagnosis of scarlet fever was made and the patient isolated. Previous to this no rash had been seen although a slight itchiness of the skin had been complained of. At the time of our examination, however, a pinkish velvety rash could be made out on the sides of the neck and upper part of the chest. The face was deeply flushed, except about the mouth. The following day the rash was well out and of typical appearance. It then became patchy and began to fade two days later. Both tonsils became covered with a grayish exudate and general glandular enlargement was present. Throat cultures showed the staphylococcus and streptococcus. Blood count on December 4 showed eosinophilia 8 per cent.; no other change noted. The case thenceforth ran an uneventful course.

CASE 6.—A hospital nurse, aged 29, on December 8, complained of chills, sore throat, headache and vomiting. These, however, were not very severe and she continued on duty. Her appetite seemed unimpaired. Two days later the face, shoulders and outer aspect of arms were found to be flushed. The tonsils were slightly enlarged and injected and the tongue coated. The following day the erythema had assumed a blotchy appearance and was limited to the regions first involved. It did not extend and was followed by a slight branny desquamation on the arms and face. During the whole course the temperature did not go above 99.

CASE 7.—A child, aged 4, was admitted to the hospital December 6 suffering from acute bronchitis; while in the ward the temperature ran from 99 to 100. On December 21 the child had a slight erythema on the trunk, legs and face and the tonsils were red and swollen. The next morning the rash was faint, the tongue was coated and the tonsils were very large. By the 25th the rash had disappeared; although the patient was under close observation no appreciable desquamation followed. The urine showed a faint trace of albumin from December 12 to December 24. The temperature was never above 100.

CASE 8.—The patient, a child aged 3, on surgical service was operated on for club-foot on December 6, and on the 7th the temperature arose to 100.5 and remained between that point and normal until December 14. On that day, although the patient had not formerly complained, the temperature arose to 102.5 and there was a slight reddish punctate eruption over the body with the face flushed, excepting the circumoral region. The tongue later presented a strawberry appearance and the tonsils were large and red. There was a general glandular enlargement. On the 20th desquamation began and the child was discharged well one month later.

CASE 9.—A nurse, on duty in the infected ward, had scarlatina accompanied by arthritis, which was not severe. Her case ran a typical course. The patient made an uneventful recovery.

CASE 10.—A laborer, aged 30, was admitted to the surgical service for a herniotomy. On December 20, four days after admission, there was a slight rash on the body with an injected throat and large, red tonsils. The tongue was swollen and coated, glands enlarged. On January 1, desquamation started and patient was discharged January 16. At no time was the temperature above normal excepting on December 29, when the wound became infected and the temperature remained above normal for a few days. The leucocyte count was 23,000, eosinphiles 11 per cent., blood-cultures negative.

CASE 11.—A miner, aged 28, had been admitted to the hospital on September 4 for paraffin injection of the nose. On December 22 the patient had swollen tonsils, a suggestive tongue and a very slight, pinkish, macular rash on the body, the macules being from 1/8 to 1/2 an inch in diameter with a slight erythema between them and looking somewhat like measles. There was no enanthem on the buccal mucosa, no nausea, sore throat or fever; but the patient had some headache and general glandular enlargement. On December 21 there was a slight desquamation on the right hip which lasted only a few days; no desquamation was noticed elsewhere. The urine showed a faint trace of albumin from December 23 to January 10; the temperature was never above 99.

---

* Read in the Section on Dermatology of the American Medical Association, at the Sixty-first Annual Session, held at St. Louis, June, 1910.

Case 12.—The patient, a nurse aged 20, on December 14 had some headache, sore throat and felt feverish, vomiting four times. On examination there was a slight erythema of the arms, over the region of the scapulæ and on the face, except the circumoral region. The patient also had a coated tongue and swollen, red tonsils covered with a slight exudate. The glands were not enlarged. By the 20th the rash on face and arms had faded, having appeared nowhere else, and on December 28, there was a very slight desquamation present on the areas involved. The nurse was discharged January 9, having never had a temperature above 100 and that only during the first night. The urine showed a faint trace of albumin up to January 6.

Case 13.—A nurse, aged 23, on December 15 had headache, sore throat, and felt chilly and feverish. The next day there was a slight rash on the chest and neck with a temperature of 100.5. The tongue was swollen and coated, and the tonsils red and enlarged. The glands about the neck showed enlargement. By the 20th the rash had disappeared but no desquamation followed. On the 24th the throat again became sore and the glands enlarged and tender with a rash over the whole body. Then typical desquamation appeared, and the patient was discharged January 10. Except during the first night the temperature was never above 100. The urine showed a faint trace of albumin for a few days.

Case 14.—A maid employed in the hospital, aged 25, on December 22 had a sore throat, headache, backache and was nauseated. She continued to work until two days later, when on examination she showed a flushed face, except the circumoral region, with erythema over the chest and shoulders. The tongue was large and coated, papillæ prominent, tonsils red and swollen and glands generally enlarged. The erythema was entirely gone by December 27, but the patient never had the slightest trace of desquamation. The urine showed a faint trace of albumin from December 25 to the 29. There were no casts. The leucocyte count was 13,600, eosinophiles 13 per cent., throat cultures gave staphylococci and streptococci. The temperature was never above 99 nor was the pulse over 100.

The remaining cases in this epidemic showed nothing unusual except that they were very mild and comparatively of short duration. The points mainly to be noted in this epidemic are the following:

1. The relatively large numbers of adults, chiefly nurses in the infected wards. Of eighteen attacked, eight were adults, six were nurses or otherwise employed in the wards, and two were adult patients exposed while in the wards.

2. The benign character of the infection and its short course, (average being 3.9 weeks from appearances of rash to end of desquamation). The only constant symptoms that could be regarded as at all typical were the onset and the congestion of the fauces. The cutaneous manifestations, with two exceptions, are evanescent and alone insufficient for the purpose of diagnosis.

The second epidemic began in April, 1907; there were eleven cases reported, although the case notes were found even less complete than in the first epidemic. As nearly as can be ascertained the epidemic began in the children's ward as an indefinite sore throat with no distinct or constant cutaneous manifestations.

Convalescence, however, was more protracted than was observed in the first epidemic and even a larger proportion of adults were attacked. The following may be taken as the most typical examples of this epidemic.

Case 15.—A nurse, aged 20, was admitted to the isolation pavilion April 19, 1907, after having had a slight sore throat, headache and malaise since April 16. On examination there was a faint rash over the entire body, general glandular enlargement, tongue negative, tonsils injected and the right one enlarged. There was nothing abnormal in the heart or lungs. The rash disappeared by April 22 and desquamation, which was never very profuse, did not start until May 1 and lasting until July. The temperature was never above 99.5, excepting at one time, when it went up to 100.3. The pulse was never more than 110; urine was negative. The patient was discharged July 1, 1907.

Case 16.—A nurse, aged 21, on July 13 complained of sore throat, weakness, nausea, cold perspiration and fever. The next day she noticed an eruption and on examination there was found a marked erythema with edema of the face. There was a strawberry tongue, throat swollen, tonsils covered with a membrane, glands all palpable. The cutaneous rash and the membrane in the throat were gone by May 18 and desquamation started lasting until July. The temperature on admittance was 104 and pulse 120, both of which came down to normal in four days. No complications were noted, excepting a slight trace of albumin in the urine. Cultures of the streptococcus were obtained from the throat.

Case 17.—A nurse, aged 20, with previous history of rheumatism and chorea, had been on duty in the infected ward. On May 9 she complained of weakness, sore throat and malaise. On the 10th a rash was noted on the chest, arms and neck and on examination there was a faint erythema over the entire body, with a strawberry tongue, swollen tonsils covered with a heavy membrane and general glandular enlargement. The throat swab showed only streptococcus. The rash was gone by the 13th and desquamation began about a week later, being finished by July. The patient developed a slight arthritis and myocarditis. The temperature remained about 101 until the 15th. The urine showed a faint trace of albumin.

Case 18.—A nurse, aged 19, awoke on May 9 with a slight sore throat, nausea, malaise and slight fever. The next day a rash was noticed and on examination the patient had a very slight erythema over the entire body with a negative tongue and injected throat and tonsils. The superficial glands were slightly enlarged. Desquamation began on the 25th, lasting until July, although never very extensive. The urine showed a faint trace of albumin; there were never any casts. The temperature was 100 on the first day, after that normal.

Case 19.—A nurse, aged 20, on May 4 complained of severe sore throat, nausea and malaise. Early in the afternoon an eruption first appeared on chest and neck. The following day a general marked erythema was present with glandular enlargement, tongue large, swollen, reddened, and throat greatly congested. The rash had disappeared on the 19th, and the throat was normal by the 21st. Desquamation began June 1 and lasted until July 17, although never very profuse. The temperature on admission was 102, but soon fell to normal where it remained. The urine showed a faint trace of albumin.

In this epidemic, as in the one preceding, there developed no serious complications or fatal results. The features to be noted are the sudden onset with marked involvement of the fauces and comparatively high temperature followed by a varying degree of the exanthem. There was a rapid subsidence of all symptoms followed by a retarded but protracted period of desquamation.

What may be termed the third epidemic occurred in 1909. Although but three cases were observed they furnished features that are thought worthy of mention.

Case 20.—A child, aged 9 months, was on the surgical service for cervical adenitis, being admitted Oct. 31, 1909. It had some discharging sinuses which were being packed with iodoform gauze, and on March 21 the child developed a slight scarlatiniform rash with a temperature of 100. The rash was faint, atypical, lasting only three days. There was no nausea or vomiting. The throat was congested and reddened, while the tonsils were enlarged. At first the case was regarded as an iodoform rash, but as the patient had 7 per cent. of eosinophiles in a differential count of 200 cells she was isolated, and while in isolation had a typical desquamation and double otitis. The urine also had a faint trace of albumin.

The temperature never went above 100 until the otitis developed.

CASE 21.—The child in the next bed to the patient last described came down three days later with a typical scarlet fever. She was a girl aged 3, in the hospital for acute anterior poliomyelitis. The rash was marked and typical, with a temperature of 103, rapid pulse, vomiting, severe sore throat and a considerable enlargement of the tonsils. Two days later the rash faded and the case ran a typical course of desquamation with eventually a complete recovery.

CASE 22.—A nurse, aged 24, was nursing the child with obscure so-called iodoform rash. Two days later she was taken off duty because of a sore throat and a feeling of malaise and headache. The throat was very red and edematous, the tonsils greatly swollen so that they met in the median line. They were partially covered with a membrane but showing no diphtheria bacilli. The glands were not enlarged, except those of the neck. The temperature was 100 on admittance, 103 two days later and afterwards never above 100. On December 1 the patient vomited several times but the tongue was never typical. The leucocyte count was 19,000; differential showed no eosinophilia; urine was negative. The patient never showed any rash or desquamation, but considering her symptoms it was deemed justifiable to place her in this list.

CHARACTERISTIC FEATURES

The most striking characteristics in this series of 32 cases occurring in three epidemics were the following:

1. *Erythema.*—There were three cases in which erythema was very slight; in one it was absent and in one it was confined to small areas and very evanescent. Two of the patients with slight erythema had it confined to the neck, shoulders and arms. It may be well to mention, in passing, that one patient had a secondary erythema.

2. *Temperature.*—This varied from normal to 105 F. Four patients never had a temperature above 99, two never above 100, and the remainder ran between 100 and 105, most of them, however, between 100 and 102.

3. *Desquamation.*—There were six cases in which the desquamation was typical and one in which it was faint but general. One patient never showed any desquamation except around the neck; another none except on the right hip. There were two in whom it was confined to the face, arms and shoulders and three never showed any desquamation.

4. *Urine.*—In only two cases was there absence of all signs of nephritis, while all the others had a faint trace of albumin; and in one case, there were casts. Two of the three patients showing no desquamation had a faint trace of albumin for a few days.

5. *Angina.*—Practically every patient in this series had a severe angina, seven of them also showing presence, more or less, of a membrane in the throat.

6. *Blood.*—The only changes noted were a marked increase in the number of leucocytes in a few cases, and in a number of instances the differential blood count showed a high percentage of eosinophiles, which is in accord with the observations of Van den Berg[1] and Kotschetkoff.[2]

LITERATURE OF THE SUBJECT

In the literature dealing with this special phase of scarlet fever, namely, the absence of exanthem with little or no rise of temperature together with other manifestations characteristic of a faint type of the disease, we find as far back as 1839, Taupin[3] observed, during the course of his internship at the Hôpital des Enfants Malades, an epidemic of five cases of scarlet fever in two of which there was no eruption. The year previously Eiselt[4] published an account of a severe case of scarlet fever in a girl of 20, in which there was no eruption, although the girl had a marked desquamation associated with anasarca. She eventually recovered.

Buttura[5] in 1857, was called on July 10, 1856, to see a young man who suffered from a well-marked scarlatinous angina. The eruption was copious and the disease followed a course typical of scarlet fever. Four days later a little girl in the same family developed croup; angina marked but no eruption throughout the course of the disease. Five days later on June 20 a little brother also developed intense characteristic anginous symptoms; the odor from the mouth was pronounced. No eruption could be observed at any time. Convalescence was prompt in all three. There were no sequelæ.

Buttura then enters into a discussion concerning the opinions of authors in regard to the possibility of scarlatina without eruption, and reviewed the literature of this subject at some length. He states that in September, 1829, there reigned in the village of Seine-et-Oise an epidemic of so-called common angina. Careful study by the local physician led to a diagnosis of scarlet fever with predominant mouth (throat) symptoms. In the Château de Villeroy, inhabited by Comte Friant and his family, thirteen persons were affected, and of these, five presented a special angina without eruption.

Trousseau observed scarlatinous angina without eruption of the skin in 1828, at Cour-Cheverny. The diagnosis was made on the strength that a boy had distinct scarlet fever with eruption. Three sisters of the boy developed fever, angina, but no eruption.

He states that Dr. Carrière observed during an epidemic at Saint-Dié (Vosges) during the winter of 1842-1843, 34 cases of scarlet fever with an eruption in 23 only, and in the majority of these it was very slight. The disease ran a benign course. In one case of scarlatinous edema with albumin in the urine; no sign of eruption appeared, although all the other symptoms of scarlet fever with angina were present.

Bouché (of Vitray) reported four cases of scarlet fever as follows: The first was typical scarlet fever without eruption; the next a typical case with eruption; the third was again without an eruption and the fourth again a usual case. Two of the cases were without eruption. The diagnosis was made from general symptoms and the presence of eruption in the other two cases occurring in the same house.

Legroux reported a case of scarlet fever in a chlorotic woman in whom the eruption could barely be made out. The eruption was likewise scarcely perceptible in an infant of four days who is supposed to have contracted it from the mother, who had scarlet fever on the second day of puerperium. The father had an angina without fever or redness of the skin at the time that the scarlet fever terminated in the mother.

In another house a boy had ordinary scarlatina; the sister developed a marked angina, with pronounced scarlet eruption and died. During the course of this affection the mother, her infant, and a young woman of

24 contracted angina with pseudomembranous plaques, with fever, but without eruption, lasting six days. Three days after the death of the child, the grandmother and the father presented guttural angina, slight fever, characterized by a bright redness, but no swelling.

During an epidemic in Berlin, Dr. Helft observed cases in which no eruption appeared although all the other symptoms prevailed, occurring in families in which scarlet fever was present.

In an epidemic of scarlet fever at Loudon (Vienne) from March to September, 1841, Mondière reported that in one case of very severe angina the eruption was confined to the feet and hands only. In other cases no eruption appeared.

During the epidemic at Loches, 1835, Renaud observed three cases of scarlet fever in one family. Two children developed typical cases of the disease when the third one was stricken with all the severe symptoms that the others had shown, but at no time during the attack did it develop the slightest sign of an eruption. The course of the disease was quite severe in this case, but the child recovered.

Berrand further states that Krauss of Tübingen reports having observed scarlet fever without eruption in the proportions of 1 in 3. The cerebral symptoms predominated in these cases. He states that Dr. Maclintock reported three cases as follows: Child was taken with vomiting; condition did not improve; coma alternating with spasms, death ensued. On the day this child was buried another in the family was taken in the same manner; developed the same symptoms; marked convulsions and death. The third child was also taken. It, however, developed a typical scarlatina rash. No doubt the other two children died from scarlatina without exanthemata.

About the time Buttura's article appeared Bauer[6] reported an epidemic of 20 cases, among them being that of a boy who had, he thought, a very severe scarlatina, yet developed no observable eruption at any time. The patient eventually recovered after having had a post-scarlatinal arthritis.

Anderson,[7] Banks,[8] Whelan,[9] Robinson,[10] Dreyfus,[11] and Brissoe and Wetherill,[12] also reported similar cases about this time, all agreeing that in their experience scarlatina at times existed with absence or sparseness of the eruption as well as other symptoms of scarlatina. At such times it is impossible to make a diagnosis were it not for the fact that an epidemic of scarlet fever is in progress.

Furthermore Gosebler[13] in 1881 made a diagnosis of scarlatina in two children aged 30 months and 6 years respectively, despite the fact that they had no eruption, desquamation or throat symptoms. He based his diagnosis on the following grounds: that the children were ill for some time, the illness in each case being with fever and repeated vomiting, followed later by large amounts of albumin in the urine; and that it was at a time when scarlet fever was very prevalent in the town and quite fatal. Furthermore several cases of scarlatina without exanthemata had been observed. In 1892 Baiss[14] reported three cases in one family with the following history: The first child was found to have a temperature of 102; the next day the temperature was normal, but the child had a slight sore throat and some enlargement of the glands of the neck; otherwise it seemed to be well. There was desquamation later, however, and a few days after the beginning of the child's illness a second child was seized with more severe symptoms, and with an eruption which resembled measles. At this time the third child became ill with a typical scarlatinal eruption accompanied by jaundice. Were it not for the last case it would have been difficult to diagnose correctly those preceding.

Lee[15] reports sixteen cases, occurring in four families in which four adults and twelve children inhabited the same building. The series is noteworthy because of the absence of the exanthem as well as some other symptoms. In the first two only was any rash observed. The first patient when seen had a fast pulse, temperature 101, strawberry tongue, characteristic rash and sore throat. In five patients the glands were neither swollen nor tender. Only three had sore throat and only two vomited. The temperature in all ranged from 101 to 102; the pulse in the children, from 140 to 148, and in adults from 130 to 134. The following sequelæ were noticed: One patient developed diarrhea, two bronchitis, and in two only was there desquamation. In two after some exposure there followed swelling of the submaxillary glands with rise of temperature and accelerated pulse. One woman, contracting the so-called scarlatina five days after labor, had puerperal fever.

Warry[16] reported an interesting epidemic of 150 cases of scarlatina with sore throat but with an absence of rash. The entire epidemic both in regard to those having rash and those without rash were found to be due to the milk supply. The author believed the cases without an exanthem to be scarlatina for the following reasons:

1. Many of the patients had desquamation during convalescence.
2. Others had kidney complications.
3. Several had arthritis.
4. Several developed otitis.

Further, it may be interesting to note that scarlatina without fever has also been recognized not infrequently and corresponds more or less with some of our cases.

D'Amore[17] reports several cases and Brunard in the past year states that he has observed a number of cases about Brussels. He mentions in particular three cases, in children, which occurred in one family. They ran an afebrile course and were mild, yet all three had typical scarlatina complications.

McClanahan[18] at Woodhull, Ill., also had the opportunity of studying afebrile scarlatina in a series of 150 cases. Many of his cases also were notable on account of the absence or mildness of the exanthem and other symptoms.

He says that in December, 1892, he was called to see a patient with a temperature of 101, pulse 100, restless and complaining of itching. She had red faucial and buccal membranes; the tonsils had a fibrinous deposit over them, no strawberry tongue. By the next day restlessness had disappeared but there was a typical scarlet fever eruption although the temperature and pulse were normal. In another twenty-four hours the throat was clear, the rash and all other evidences of scarlatina had disappeared and the patient had no further trouble.

From this time until 1893 he saw about 150 cases. The fauces were involved in every case, as was the presence of the strawberry tongue. In about one-third of the cases there was no eruption. In six of them it resembled that of rubeola and in three the surface was nearly scarlet, red, smooth and glossy but without the minute points seen in the scarlatina rash. In the remainder the exanthem was the ordinary scarlet fever rash except that its stages were of shorter duration.

Twenty of the cases were followed by otitis; this occurred irrespectively of the other symptoms. The temperature seldom rose above 102, and this fever rarely lasted longer than three days; in fact, in the majority, the temperature was normal by the third day. At times the disease appeared to be contagious, at other times not.

Rodger y Piza[19] had the opportunity of observing an interesting case. In a certain family there was a child who ran through a typical course of scarlatina. Rodger y Piza was suddenly called in to see a younger child who had had a high fever for twenty-four hours and was voiding dark urine. The latter on examination was found to contain blood, epithelial cells, casts and much albumin. The hematuria lasted for thirty days. On the twelfth to the fourteenth days there occurred a slight furfuraceous desquamation on the face and upper part of the chest and forearms. From the presence of scarlet fever in the house Rodger y Piza had not the slightest doubt that this was a case of scarlatina *fruste,* so called by Trousseau, only one symptom of scarlet fever being present.

THE VARIATIONS OF SCARLET FEVER

From the foregoing it seems evident that what is known as scarlet fever varies greatly in its clinical manifestations. In a violent form it may cause death within a few hours, or in its mildest form it may be evanescent and difficult to recognize. As to the *materies morbi* which gives rise to scarlet fever we know nothing positively, nor of its mode of invasion. From the epidemics herein reported as well as others cited it would appear that the toxin varies in different outbreaks. From our observation it does not appear that mild infections beget malignant strains, or the reverse. Furthermore it should be remembered that in epidemics of a severe type atypical cases occur as frequently as in those of mild type.

From the fact that the tonsils are involved at a very early stage, and from the constancy with which this symptom has been noted, it would seem that the infecting agent gains access through these glands, as claimed by Dawson[20] and Lemoine.[21]

It seems unwise, therefore, with our imperfect knowledge concerning the etiology of scarlet fever, to regard these aberrant forms, which point strongly to some aberration of the exciting cause, as distinct affections. In 1894 Duke[22] endeavored to establish a "fourth disease" in the infectious exanthemata, but the consensus of opinion does not substantiate this claim. Our observations show that the most constant symptoms are the angina and slight nephritis, while an increase of eosinophiles in the blood was observed in a considerable number of our cases. Other phenomena are usually present even in atypical forms of the disease, but they are inconstant and subject to wide variation.

1935 Euclid Avenue.

ABSTRACT OF DISCUSSION

Dr. W. L. Baum, Chicago: I think that all of us who have had much experience with scarlet fever realize the great difficulty attendant on a correct diagnosis in these atypical cases. In Cook County Hospital in Chicago a number of cases have caused much controversy among the health authorities, the attending physicians and physicians in general practice. In attempting to reach a diagnosis in these cases, we have paid particular attention to the blood examination rather than to the local manifestations of the disease, and in our blood tests we have not laid so much stress on the absence of eosinophilia as on the differential blood count. We have elaborated somewhat on the theory propounded by Tillotson; that is, we have paid especial attention to the increase in the polynuclear nutritives, and so positive have we become that on that point alone do we exclude or admit the cases. We have had cases so mild that they would otherwise have escaped recognition. On the other hand, we have had cases in which the skin and throat manifestations were so manifest and pronounced that one would be led to the positive diagnosis of scarlet fever, and yet, on account of the presence of some other factor, such as a wound infection, a contrary diagnosis was established on the basis of the blood count. About three years ago I remember seeing a child with a small scalp wound, and at the same time there suddenly developed a slight temperature and sore throat, together with an erythematous rash commencing over the shoulder and extending to the sternum and other parts of the body. There seemed to be no question that the case was one of scarlet fever. When I saw the child on the following day, I was induced to make a blood count on account of the presence of the wound on the head, and as a result of the findings, scarlet fever was excluded. In the meantime, the child had been quarantined in the scarlet fever ward, and six days later it developed true scarlet fever, which proved fatal. I am convinced that it is on the basis of these blood counts that the differential diagnosis in these doubtful cases of scarlet fever can be made more positively than by any other means known at the present time.

Moving Pictures of the Internal Organs.—The *Zeitschrift für Röntgenkunde* opens the year and its twelfth volume with an article by C. Kästle, H. Rieder and J. Rosenthal on the kinematographic reproduction of the physiologic movements of the stomach. They describe the apparatus for the purpose and give a series of the moving pictures and also a composite view of the stomach in normal conditions and in a case of cancer. They found that a fold forms in the stomach wall above the pylorus and protrudes inside, the fold of the stomach wall growing longer and longer, the tip curving around more and more toward the pyloric outlet. As the movements of this fold are traced in the moving pictures it is seen that the fold appears like a kind of shovel, and forces the contents of the stomach out through the pyloric outlet, after which the fold retrogresses, to form anew and go through the same procedure again. In a case in which cancer was suspected, the rudimentary protrusion and behavior of this fold confirmed the presumptive diagnosis of some serious disturbance in the physiologic movements of the stomach. The authors assert that this "bioroentgenography" is destined to prove valuable in the diagnosis of pathologic conditions.

SPONTANEOUS RUPTURE OF THE EYEBALL

A PHENOMENON OF GLAUCOMA *

E. C. ELLETT, M.D.
MEMPHIS, TENN.

AUTHOR'S CASE.—Mr. S. C., aged 68, resident of Kentucky on a visit to Memphis, had been given a letter of introduction to me by Dr. J. M. Ray of Louisville. On the night of Dec. 9, 1904, about 9 o'clock, I was called to see him on account of a sudden pain in his left eye, accompanied by bleeding. He had undressed and retired, and afterward felt a desire to go to stool. His bowels moved without straining, and he again retired. After lying down he began to bleed from the left eye, and immediately to experience a severe pain. I found him still suffering such pain as to require half a grain of morphin to relieve him. The eye showed a large clot protruding from a rupture in the cornea, the corneal wound being about 10 mm. long. Oozing of blood was still going on, and the eye was so painful that pressure could not be applied. The bleeding continued for an hour and a half, finally ceasing from the effect of ice-pads lightly applied, or the morphin, or else spontaneously. A light dressing was then applied, and on December 12 the eye was enucleated.

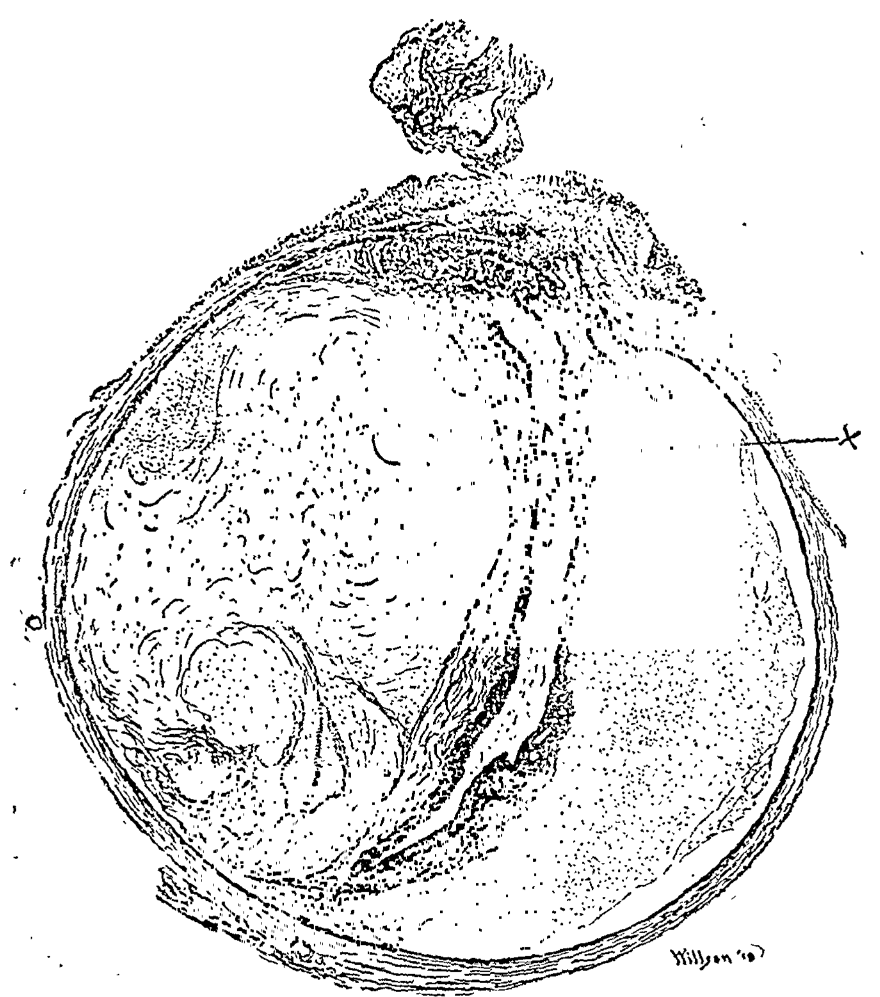

Fig. 1.—A section of the globe under low power. The swollen corneal tissue, infiltrated with round cells, is seen, with a mass attached to it consisting of blood and ocular membranes. The tear in the cornea can be located by tracing Descemet's membrane. The cleft in the center of the ball is formed by folds of the chorioid. At X is a portion of the retina. Between the chorioid and sclera is a large hemorrhage, which has detached both chorioid and ciliary body, folding the latter forward against the iris. The lens is not seen. The section passes well to one side of the disk.

The previous history of this patient is gathered from Dr. Ray's notes, of which he has kindly sent me extracts. Dr. Ray had seen the patient, aged then 65, first in 1901, for an iritis in the right eye. This subsided, with vision 20/30. The left eye, in December, 1901, showed floating opacities in the vitreous, opaque lens striæ and some plastic deposits on the anterior capsule, with synechia. The patient counted fingers at two feet. In 1904 Dr. Ray saw the patient again, with increased tension in the left eye, ciliary injection and hazy cornea. The condition was controlled by physostigmin (eserin), and operation was declined. A few weeks before I saw the patient Dr. Ray examined the eye again. The iris was almost completely adherent to the lens, and looked muddy; the cornea was normal, eye blind, and there was some ciliary injection and lacrimation, tension normal. There was extensive destruction of the framework of the nose, and an old specific history.

To return to what I can relate from personal observation, there was marked arteriosclerosis, urine and heart normal. No cause for the rupture was discovered. There was no history of any sort of injury or straining or effort, if we accept the patient's statement that he had not strained at stool. The eye had been a little red and painful for two or three days, and it is reasonably sure that this was due to or accompanied by an increase of tension, judging from the history as related, and the microscopic appearance of the nerve-head, as subsequently determined. The eye was enucleated under ether and without any accident. The socket healed in the usual time.

The right eye was found to be the seat of an incipient cataract, vision 20/80, with — .75 S. with — .50 Cyl. Ax. 140° = 20/40, add × 3 S. = J. iii. The retinal veins were tortuous and indented by the arteries; arteriosclerosis was present. The nose and pharynx both showed evidences of former specific ulceration, in the shape of extensive scars.

The patient died in the summer of 1909, and as far as could be ascertained the right eye remained good. The cause of death was not learned.

The eye was sent to Dr. Brown Pusey, to whom I am indebted for the report on the condition of the eye, as follows:

"Macroscopically a section in the antero-posterior diameter shows a hernia of the ocular contents through the center of the cornea. The retina and chorioid are detached except at the nerve-head, and these tissues make up the mass of the hernia. The space between the sclera and the detached chorioid and retina is occupied by blood (Fig. 1). The head of the nerve shows deep cupping.

"Microscopically the corneal tissue shows inflammatory changes of marked degree. The tissue is edematous and there is a great increase of cellular elements. There is no necrotic material such as one would find in an ordinary ulcer. The tissue of the limbus region shows the same changes; the new cells here are mononuclear cells. The arteries of the limbus region have markedly thickened walls, and in one set of sections marked inflammatory changes are seen in the outer wall of a large vein (periphlebitis). The prolapsed tissue is made up of vitreous, iris, chorioid, and retina, and all of them are edematous and full of blood. There is little to be made out of a study of the iris, chorioid, and retina except the fact that the iris and chorioid are the seat of a great increase of cellular elements, and the vessels show marked thickening of the walls. (Figs. 2 and 3).

"The most striking changes found in the tissues are the changes in the cornea and the changes in the blood vessel walls. These changes probably explain the bursting of the eyeball and the hernia of its contents."[1]

The peculiar features of this case (I had never encountered a similar one, and Dr. Ray, a practitioner of much larger experience, apparently also had never seen a similar one) led to some search into the literature of the

---

* Read in the Section on Ophthalmology of the American Medical Association, at the Sixty-first Annual Session, held at St. Louis, June, 1910.

[1] Dr. Pusey adds that in his opinion the cornea ruptured first and the blood vessels later from the sudden lowering of intra-ocula pressure. The probable sequence of events will be discussed later, but it would be well to say now that in forming an opinion from examination of the sections one must take into consideration the fact that the eye was not removed for several days after rupture, so that the inflammatory changes in the cornea had time to occu after rupture and before the eye was removed. It cannot be argue from the sections that the cornea was pathologic at the time o rupture.

subject. In all, twenty-two cases have been collected, one reported in 1879 (Cheatham), one in 1881 (Vergely), and the others since 1899. The references quoted by Coppez of cases reported by Baster, Kyll, and Flemming, could not be found. The cases of McKenzie, if they are the ones referred to on page 449 of his book,[2] also quoted by Coppez, are cases of perforating corneal ulcer and not at all similar to the condition under consideration.

The following are the abstract reports of the twenty-two cases referred to:

Vergely's Case.[3]—A woman, 78 years old, with failing vision for three years, and opacity of the right cornea, arose one night and made an effort to urinate, after three days of pain in the right eye. A severe pain was felt in the right eye, followed by a free flow of blood from it. This was found to proceed through a tear in the center of the cornea. The bleeding ceased spontaneously, and the ball atrophied. Vergely thinks that the eye was glaucomatous, and that an intraocular hemorrhage occurred, which raised the tension sufficiently to rupture the cornea. The left eye showed a cataract.

Coppez's Case.[4]—A man, aged 69, had double chronic glaucoma. The right eye had been iridectomized, and showed cupping and atrophy of the disk, with impaired vision and contracted field. The left eye, not operated on, was almost totally blind. The left eye subsequently ruptured during a violent fit of anger, the rupture being characterized by severe pain and free bleeding. The eye atrophied and was removed nine months later. The lens was absent, the chorioid and retina detached, but not expelled.

Professor Coppez's Case (quoted by H. Coppez).—A man, aged 65, had absolute glaucoma in the quiescent stage. Leaning to look under his bed, he was seized with a severe pain in the eye, followed by a free hemorrhage. A central rupture of the cornea was found, from which the ocular contents protruded. The eye atrophied. As this eye had not been seen immediately before the accident, it is not certain that the cornea was not ulcerated.

Wibo's Case.[5]—A woman, aged 65, with the left eye normal, had absolute glaucoma, with exacerbations in the right eye, controlled by pilocarpin. A whitish infiltration extended from the center of the cornea toward the periphery. During a slight effort the eyeball ruptured, and with a profuse hemorrhage the ball emptied itself of its contents and membranes. A horizontal tear occupied two-thirds of the corneal diameter, with ulcerated borders. Evisceration was performed.

Villard's Cases.[6]—*Case 1.*—The patient, aged 65, had simple chronic glaucoma in the right eye. One month after the first examination an attack of acute glaucoma occurred, for which an iridectomy was performed. A year later the eye, which had been comfortable, but had become blind, again became painful and an ulceration of the cornea was observed. This ulcer became infected and the ball ruptured suddenly with hemorrhage and such severe pain as to cause the patient to lose consciousness. The ball atrophied, and about eighteen months later the patient died from softening of the brain.

Case 2.—The patient, aged 74, had absolute glaucoma of the left eye, with pain and hyphemia. Fourteen months later the conditions were about the same, with the addition of superficial ulceration of the cornea. The lower portion of the cornea was slightly bulged. Rupture of the cornea occurred, with subsequent atrophy.

Case 3.—The patient was a man aged 65, with traumatic corneal ulcer, hypopyon, chronic dacryocystitis and increased tension. During an effort at defecation the ball ruptured at the site of the ulcer, severe hemorrhage occurred and expulsion of the ocular contents. The ball atrophied.

Verhoeff and Spalding's Case.[7]—A man, aged 64, had glaucoma, diagnosed as secondary. After two attacks of acute glaucoma, treated medically, he was free from pain for two years. He then had a third attack of glaucoma, at which time the cornea showed a complete yellowish infiltration. Enucleation was refused, and after five weeks the eye ruptured while the patient was quietly talking to his wife. The ball was enucleated. The ocular contents and membranes were found to be extruded. The edges of the corneal wound were infiltrated with polynuclear leucocytes. The globe contained a small round-celled sarcoma.

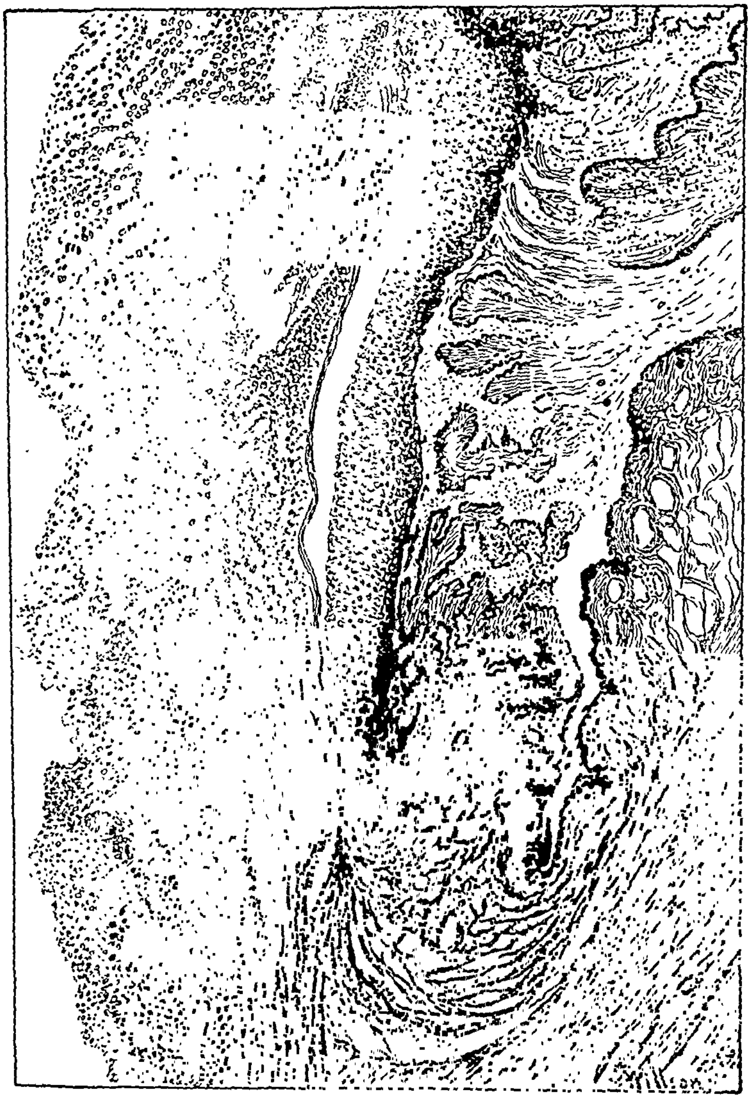

Fig. 2.—The iris, ciliary body, cornea and angle of the anterior chamber are shown under higher power. The thickening and infiltration of the cornea, the tear in the cornea and the detachment and folding forward of the ciliary body are shown.

Millikin's Case.[8]—The patient was a woman, aged 68, blind from absolute glaucoma in both eyes. While she was quiet in her room one eye ruptured, producing a vertical tear of the cornea, extending into the sclera above. Profuse hemorrhage and subsequent atrophy occurred. There was no history of any corneal disease.

Zimmerman's Case.[9]—A healthy woman, aged 56, had a corneal ulcer involving one-half the corneal thickness and almost its entire area, in an eye previously damaged by glaucoma. Without apparent cause the ball ruptured, the tear being horizontal and about 7 mm. long. A large hemorrhage, carrying with it the crystalline lens, occurred. The ball was enucleated.

[9] Zimmerman, M. W.: Ophth. Rev., 1899, xviii, 141; Ophth. Rec., April, 1902.

Terson's Case.[10]—A woman, aged 71, with chronic glaucoma in the left eye for eight years, had been blind one year. She had many attacks of pain. A vertical rupture of the cornea was found, with protrusion of the contents of globe. The patient had experienced a violent pain in the eye after going to bed, but this subsided and she went to sleep. An hour later she awoke to find that a hemorrhage had taken place. The protrusion was cut off and the ball healed.

Gamo Pinto's Case.[11]—A woman, aged 63, had absolute glaucoma in the left eye. The right was also glaucomatous, and was operated on (iridectomy) with good results. The cornea of the left eye ulcerated later. After two weeks the cornea ruptured, followed by a profuse hemorrhage and expulsion of the ocular contents and membranes. The eye was enucleated.

Cheatham's Case.[12]—A woman, aged 65, born blind in the left eye, for four years had been subject to attacks of severe pain, lasting several weeks. During such an attack the ball ruptured, the lens escaped and a profuse hemorrhage followed. The ball was enucleated, and the retina and chorioid found to be detached and the ball filled with clotted blood.

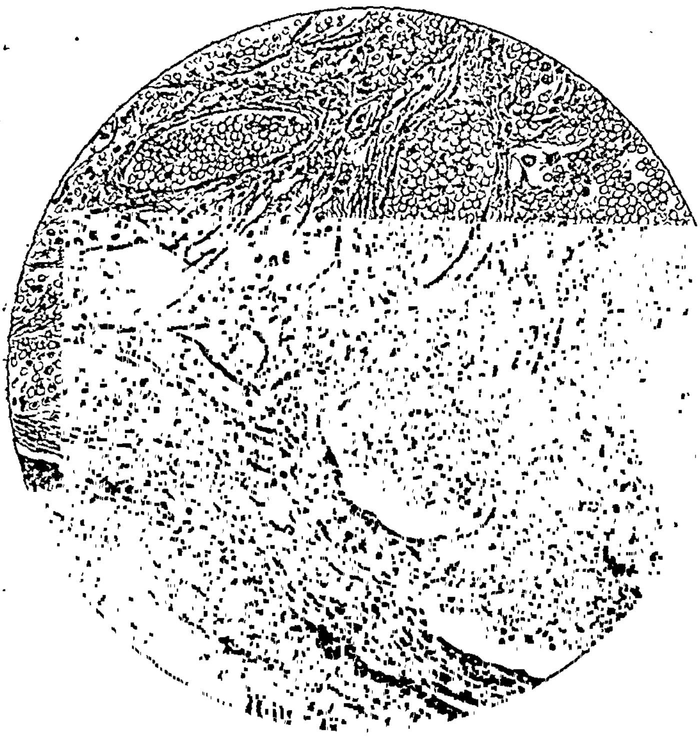

Figure 3.—A section to show the chorioidal vessels under higher power

Bialetti's Cases.[13]—*Case 1.*—The patient was a man, aged 70. The right eye was lost from trauma. For ten months he had had attacks of acute glaucoma in the left eye. In both eyes tension was + 3, the diagnosis being absolute glaucoma with cataract in the right eye, and recurrent glaucoma in the left. The lens was extracted from the right eye with loss of a "quantity of vitreous and blood." In the left eye sclerotomy, and later, iridectomy, was performed. The right eye atrophied, and three years after the operation the left eye ruptured, with violent pain, hemorrhage and loss of the lens and vitreous. The cornea was ruptured parallel with its circumference. The protruding mass was excised and the eye became quiet.

Case 2.—A man, aged 75, had glaucoma in the right eye for thirteen years, during which time he had undergone iridectomy. Rupture of the ball occurred with hemorrhage and extrusion of the ocular contents. Excision of the protruding mass was followed by atrophy of the ball.

Lissigyn's Case.[14]—A woman of 65, blind for a year, had severe hemorrhage with a rupture 4 or 5 mm. long in the lower third of the cornea; described as a perforating ulcer due to glaucomatous degeneration.

Gilfillan's Case.[15]—A woman, aged 87, with paralysis agitans and poor mental and physical condition and arteriosclerosis, had senile cataract and large corneal opacities in each eye, but no staphyloma; no note as to tension. While lying in bed she experienced a sharp pain in the left eye, and when the house surgeon reached her there had been a large hemorrhage from the eye, with expulsion of the lens and prolapse of the iris. The protruding mass was cut away and the eye healed. The rupture was in the center of the cornea and large enough to permit the lens to escape.

Fage's Case.[16]—A man had absolute glaucoma, with exacerbations, in the left eye. At one visit for such an attack the cornea was noted to be sound. Two and a half months later he returned with a horizontal central rupture of the cornea, 3 mm. long. There was no escape of the ocular contents, though the anterior chamber was filled with blood and clots lay in the corneal wound. Enucleation was performed.

Shepherd's Case.[17]—A woman, aged 81, had chronic glaucoma in one eye for a few years. The eye was blind and for a week had been painful. One night the ball burst across the middle of the cornea, this being followed by free hemorrhage and partial escape of the ocular contents. The eye was removed. The cornea did not show any evidences of ulceration.

Ingalls' Case.[18]—A woman, aged 89, had been blind in the right eye for two years. Following a severe pain the eye ruptured, with free hemorrhage and protrusion of the iris through a rent in the lower half of the cornea. The eye was removed and the whole contents found to have been expelled. The margins of the corneal perforation were smooth and not ulcerated.

Hauenschild's Case.[19]—A woman, aged 28, with apparently normal eyes, was seized with a violent pain in her right eye. The next day there was widespread subconjunctival and subpalpebral ecchymosis, and slight exophthalmus. The anterior chamber was entirely filled with blood. The eye was blind. When the blood was absorbed a rupture was seen in the sclera, 1 mm. above the corneal border, into which the iris had prolapsed. The rupture was 6 mm. long and concentric with the corneal border. The blood was absorbed and the eye shrunk. The other eye was normal.

Houdart's Case.[20]—A man, aged 72, was blind in both eyes from glaucoma. The right eye was affected also with a cataract and had been blind four years. While working in a stooping position cutting grass, the patient was suddenly siezed with a frightful pain in the head, vision seemed red, and he fell unconscious to the ground. Three hours later the cornea was found to be ruptured through the middle, an abundant hemorrhage had occurred and the lens and probably other ocular contents had escaped. No intervention was allowed.

Ball's Case.[21]—Ball merely mentions that he has seen such a case.

It will be noticed that the patients, with one exception (Hauenschild), were old people, aged from 56 to 89. Indeed, with the single exception of Zimmermann's patient, aged 56, none were less than 63. In two instances (Fage and Ball) the age is not mentioned. Hauenschild's case is evidently in a different category from all the others, and, excluding this case, the patients were all the subjects of chronic glaucoma. In many of them this was established before the rupture of the eye; in others the subsequent examination or previous history makes the presumption of glaucoma plainly justifiable. The hemorrhage in all cases proceeded from the vessels of the chorioid, and the rupture of the ball occurred in the cornea. In nearly all of the cases these phenomena were spontaneous, there being usually no apparent cause, such as trauma or straining. We might profitably consider this condition, since the number of cases reported indicate that it is not so rare as not to be of general interest, and inquire how it happens, when and why it may happen, and what is our duty in case it does happen.

[21] Ball, J. M.: Modern Ophthalmology, Philadelphia, F. A. Davis and Co., p. 418.

In inquiring how spontaneous rupture of a glaucomatous eye comes about, we find a difference of opinion among those who have observed it. Some assert that the rupture of the cornea is primary, and due to the perforation of an ulcer, or the traumatic rupture of an ulcerated or otherwise weakened cornea, the resulting lowered tension permitting the unsupported intra-ocular vessels to break, with resulting hemorrhage. Others contend that the intra-ocular hemorrhage is primary, and that the increased tension causes rupture of the cornea, which may or may not have been previously weakened by disease.

Whichever view we consider, it can be justified by analogy, which is well, since in a given case one cannot always be sure of the sequence of events. In favor of the idea that the rupture of the cornea is primary and the hemorrhage secondary, the occurrence of chorioidal hemorrhage during a cataract extraction could be cited. Here we see the rupture of the chorioidal vessels occur when the corneal incision and evacuation of aqueous has lowered the pressure which supports the vessels. In support of the other theory, that the hemorrhage is the primary event, the occurrence of cerebral hemorrhage might be regarded as analogous. With or without apparent exciting cause, but presumably accompanying an increase of blood-pressure from some cause, the diseased vessel breaks. The question now arises whether a hemorrhage from the choroidal vessels can increase the intra-ocular pressure to such a point that rupture of the cornea will follow. Among those who have reported cases a difference of opinion is found. Villard, Verhoeff and Spalding, Valude (discussing Terson's cases, q. v.), Gamo Pinto, Bialetti and Lissigyn, express themselves more or less emphatically to the effect that the sequence of events is, first, the rupture of an ulcerated cornea, and then the hemorrhage. Verhoeff and Spalding, in particular, question the possibility of a hemorrhage raising the pressure enough to rupture the cornea, since the intra-ocular pressure is already as great as, and dependent on, the blood-pressure. A rupture of an intra-ocular vessel, then, does not, according to these observers, increase the intra-ocular tension. On the contrary, Wibo, Gilfillan, Millikin, Fage and Ingalls think that the hemorrhage preceded, and presumably caused, the rupture in the cases they observed. Shepherd says that the cornea in his patient was normal, and to the best of my belief it was so in my patient as well.[22]

In cases not observed before rupture it may be hard to tell, since all of the ulcerated corneal tissue may be torn away by the passage of the blood and membranes through the rent. While the pathologic report on the case herewith presented speaks of infiltration of the cornea, the fact that enucleation was not done till three days after the rupture gives a sufficient interval to permit these changes to have taken place after the accident. In this connection I would call attention to the drawings of the microscopic sections.

In reference to the point raised by Verhoeff and Spalding, we now believe that the intra-ocular fluids are not secretions, but the product of a filtration process. Such a filtration can take place only when the pressure in the blood-vessels, whence the fluids come, is greater than the pressure within the eyeball, into which the fluid filters. The intra-ocular pressure cannot exceed the blood-pressure, but, on the other hand, it would seem that the blood-pressure must exceed the intra-ocular pressure. It has been shown experimentally[23] that when the intra-ocular pressure is raised to 50 mm. of mercury filtration ceases. This would indicate the intravascular pressure, which is about twice that of the normal intra-ocular pressure. If this is correct, then blood escaping into the eye with a *vis a tergo* equal to the intravascular pressure could exert sufficient force to rupture a weakened cornea.

The occurrence of this distressing accident is predicated on the existence of several conditions. A study of the reported cases would justify one in saying that these conditions are glaucoma, vascular disease and probably an ulcerated or otherwise weakened cornea.

Glaucoma, on theoretical grounds, would not appear essential to the occurrence of this accident, but, in fact, it is present with too great regularity to be regarded as a coincidence. The vascular changes, with increased blood-pressure, necessary to produce the condition in question, seem always to produce glaucoma, a fact easily understood in the light of the now general appreciation of the close relation between glaucoma and vascular disease.

The vascular changes have been more often inferred than demonstrated in the reported cases. While arteriosclerosis is often mentioned as being present, the conditions of the blood-vessels in the enucleated eye are mentioned only by Coppez and Ingalls. Degenerative and proliferative changes in the blood-vessels of the retina and uveal tract are described by these writers, those in the uveal tract being the ones that concern us most. The changes described and illustrated in my own case may be regarded as typical.

It is well known that hemorrhage into a glaucomatous eye may occur without producing rupture of the cornea. Such a case is described by Graefenberg,[24] and they are probably not very rare. They are sometimes erroneously referred to as cases of hemorrhagic glaucoma.

In the absence of the necessary degree of vascular degeneration and increased blood-pressure, the cornea can be ruptured or destroyed in a glaucomatous eye, without precipitating a hemorrhage. The commonest example of this is when an operation, involving corneal section, is performed for the relief of glaucoma. In addition to these common instances, two cases have come under my notice which still further emphasize this point.

---

[22] It is interesting to note that at the end of the abstract of Houdart's case appearing in the Annals of Ophthalmology (xv, 603), the reviewer doubts the possibility of any intra-ocular hemorrhage having sufficient force to cause a rupture of the cornea, and thinks that the hemorrhage was probably spontaneous, but the corneal rupture almost certainly caused by the patient striking the eye when he fell unconscious to the ground.

[23] Niesnamoff: Arch. f. Ophth, 1906, xlii, 4; Quoted by Parsons: The Pathology of the Eye, New York, 1906, iii, 967. G. P. Putnam's Sons.

[24] Graefenberg: Arch. f. Augenh., September, 1906, lvi, 1; abstr. in Ann. Ophth., 1907, xvi, 355.

A woman, aged 60, without manifest vascular disease, was attacked with glaucoma in the right eye in September, 1907. Although repeatedly advised by her physician to be operated on she would not consent. I was asked to see her on July 13, 1909, and found the whole cornea destroyed, its place being occupied by the iris, covered with granulations. Enucleation was performed without accident.

A little boy, aged 5, was brought to me for an injury to his right eye from a fall. I found buphthalmia and extensive corneal rupture. There was no intraocular hemorrhage, doubtless owing to the normal condition of his blood vessels. The eye was enucleated.

This is an occurrence, then, that must be put in our category of possibilities in cases of chronic glaucoma of the subacute or chronic congestive type. Simple glaucoma apparently does not cause it, and acute glaucoma would probably cause a scleral ectasia (ciliary staphyloma) instead.

The indications for treatment are briefly stated. The eye is lost and in general should be removed. If not it will atrophy. There is no exception to this in the reported cases in which the eye was not removed. No sympathetic trouble seems to have been so far observed to follow the retention of an eye so damaged, one cause of its non-occurrence being the advanced age, and consequent short subsequent lives, of the unfortunate patients.

Randolph Building.

ABSTRACT OF DISCUSSION

DR. J. M. RAY, Louisville, Ky.: I saw the case reported by Dr. Ellett and had the man under my care for a long while before Dr. Ellett saw him, first at his home, when he was suffering from iritis in one eye, and later on in the other. It continued to recur at long intervals first in one eye and then in the other, up to the time I last saw him. Each attack of iritis was accompanied by increased tension. The iris presented a number of adhesions to the lens capsule and was atrophic. The cornea would become hazy during these attacks and the vitreous contained floating particles. The inflamed condition of the iris and the opacities in the lens and vitreous interfered with a satisfactory ophthalmoscopic examination. The patient while under my care showed nothing more unusual than a relapsing iritis of a subacute character, accompanied by increase of tension during the attacks only. Stigmata of former specific disease in pharynx and nose were present. I advised him to have an iridectomy done, not so much because of tension, which was never very great at any time I saw him, but to check the relapsing iris inflammation that was leading to degenerative changes in the ciliary body and chorioid. I can see very well how an acute glaucoma could have developed between the time I last saw him and the time of Dr. Ellett's visit. I believe that tension in an eye otherwise degenerated from an old irido-chorioiditis could have produced sufficient interference with the nutrition of the cornea to lead to its rupture, and then the hemorrhage, occurring as a result of the removal of the normal resistance on the walls of the sclerosed retinal and chorioidal vessels.

It would seem to be impossible that the tension in an eye from rupture of a blood-vessel in its interior could be greater than the pressure in the blood-vessel that was the seat of rupture. Therefore, knowing the great resisting power exerted by the ocular tunics, it seems unreasonable for such a condition to take place in an eye where the ocular structures are of normal resistance.

From a consideration of the report made by Dr. Ellett and the eye as I saw it, it appears to me an ideal case for the occurrence of such a condition. Relapsing attacks of iritis, each attack accompanied by glaucomatous symptoms, with, eventually, degenerative changes in all the ocular structures, are the ones in which acute hemorrhagic glaucoma are liable to occur. While I feel sure the patient did not suffer from corneal ulceration, the changes preceding the fulminating glaucoma were such as would interfere seriously with the nutrition of his cornea and make it less resistant to an acute attack of tension.

Three weeks before he was seen by Dr. Ellett he presented some ciliary injection, no great tension, a degenerated iris, and a hazy cornea. I gave him a letter to Dr. Ellett, fearing he might have trouble while on his visit to Memphis. I have no note of the arterio-sclerosis, but his family physician had been treating him for rheumatism. He died most probably from cerebral hemorrhage, as near as I could get at the facts on inquiry.

DR. S. L. LEDBETTER, Birmingham, Ala.: Last fall, at the meeting of the Southern Medical Association, at New Orleans, I read a paper in which I reported a case of double glaucoma with ruptures occurring at an interval of a year. The case was first seen by Dr. Sibley, of Birmingham, and the eye removed after the rupture. Just one year later I was called to see the same patient under similar circumstances; the ball had ruptured. The history, as I got it, showed clearly an inflammatory glaucoma. There had been a history of severe pain for two or three days, with intense pain just before the rupture, and when I saw the case there was a wide, open wound, and the ball was filled with clot. The patient was an elderly woman, 65 years of age, with probably arteriosclerosis. I learned that she died two or three months after the last operation. I do not know the cause of death. The case was interesting to me because of the history of having lost both eyes from the same condition. The attending physician told me he had seen her but once or twice before sending for me; that the eye was in an inflammatory condition, with a haziness of the cornea. Dr. Ellett was at the meeting at New Orleans, but left before I read my paper, so I do not charge him with any negligence in not mentioning my case.

DR. R. H. T. MANN, Texarkana, Tex.: I agree with Dr. Ray that the intraocular hemorrhage had nothing to do with the rupture of this cornea, or it does not ordinarily. I have a patient, a physician, who came into my office with a degenerated eye and said: "I want to show you something very peculiar about this eye." He held his head down, and immediately the anterior chamber filled with blood. I do not know the cause of it, but he said it had been so for years. He could produce the hemorrhage at any time. I could not see the back of the eye. I advised him to have it enucleated. He still has the eye. I have seen it a number of times. It certainly shows to me that the blood in the eye would not produce the rupture.

DR. E. C. ELLETT, Memphis, Tenn.: Since the presession reprints appeared Dr. Lewis H. Taylor has written to call my attention to a case which he reported to this Section in 1908 (*Tr. Sect. on Ophth., A. M. A.*, 1908, p. 125) in discussing Dr. Black's paper on "Cardio-vascular Diseases." This was overlooked because titles were consulted in searching for other case reports. Dr. Taylor's case was one of repeated intraocular hemorrhages, with resulting increase of intraocular pressure and rupture of the ball, somewhat different in character from the other cases which I have quoted. In addition to one case reported by Dr. Verhoeff, which I have quoted, he has called my attention to another case of rupture associated with chorioidal sarcoma reported by him in the *Archives of Ophthalmology*, 1904, xxxiii, No. 3. He has also protested against what I had to say in regard to his views on the question of whether the corneal rupture or the hemorrhage was the primary incident. I am glad to quote from his letter, and to say that it was far from my intention to misrepresent anyone, nor can I see that I have done so:

> "In your discussion of the case of rupture of the cornea due to intraocular sarcoma reported by Dr. Spalding and myself, I think you give a wrong impression as to our view in regard to the cause of the rupture. In the first place we did not come to a positive opinion as to whether the hemorrhage was primary or secondary, but at that time simply regarded it as more probable that it was secondary. You state that 'a rupture of an intraocular vessel then, does not, according to these observers increase the intraocular pressure.' What we actually said was that 'it is doubtful if an intraocular hemorrhage would appreciably increase the pressure in an eye already under a high tension, for the increase in pressure could be no greater than the difference between the pressure of the blood within the ruptured vessels and the pressure already present in the eye.' What we meant by this was that since the eye had been under an extremely high tension for several weeks, as indicated by the clinical history, the added pressure due to an intraocular hemor-

rhage would probably be too slight to explain the rupture of the cornea if the latter was intact, and if the latter was ulcerated it would be more reasonable to suppose that the ulcer was due to high tension. You imply that we did not know that the intraocular pressure of a normal eye is much less than the blood pressure. This fact is of course known even to a tyro, and the above quotation shows that we were aware of it. You will be interested to know, however, that I later definitely determined that the hemorrhage was primary in this particular case. I am sending you a reprint in which I explain this (page 248, Case 3). In this paper I also report another case of the same kind (Case 2) which I am sorry that you could not have included in your list. In this paper also you will notice that I call attention to the case with which an intraocular sarcoma may be overlooked in an eye filled with blood, and I have no doubt that many have been so overlooked. In regard to spontaneous rupture of the cornea in glaucoma in general I am sure that the hemorrhage may be either primary or secondary, but as to which is the more frequent I am still undecided."

LUTEIN EXTRACT IN THE TREATMENT OF DECREASED MENSTRUATION AND THE PREMATURE MENOPAUSE

ELLICE McDONALD, M.D.
NEW YORK

Disturbances of menstruation are always difficult of treatment. The factors which cause and control menstruation are so little known and understood that treatment is largely empirical and experimental. Investigation into the function of the ovary and its influence on menstruation and pregnancy are, however, beginning to shed new light on these processes, and give hope of the relief of these conditions by scientific treatment.

INTERNAL SECRETION OF THE OVARY

The function of the ovary and the effect of its internal secretion are becoming better understood, and the influence of the corpus luteum on menstruation and pregnancy are now being studied experimentally in animals.

Brown-Séquard[1] appears to have been the first to suggest an internal secretion for the ovary and supposed that it was concerned in the secondary sexual characteristics. Since then many investigators have sought the presence and mechanism of the production of this internal secretion. Gustav Born[2] first suggested the hypothesis that the corpus luteum of the ovary was a gland with an internal secretion which affected the uterus and presided over the nidation and development of the ovum. Fraenkel,[3] by means of extensive experiments claims to have maintained Born's hypothesis that the corpus luteum is a gland with an internal secretion and that the corpus luteum causes the menses. He claims that as the corpus luteum is an organ sharply defined from the rest of the ovarian substance, and surrounded by connective tissue, histologically it resembles a gland, being similar to the liver or suprarenal. He holds that there is no essential difference between the true and false corpora lutea, which are ovarian glands controlling the nutrition of the uterus from maidenhood to menopause and causing insertion and development of the fertilized egg, and menstruation when the egg remains unfertilized.

TROPHIC INFLUENCE OF CORPUS LUTEUM

These facts are upheld by a long series of his experiments on rabbits, in which he found that if the corpus luteum was destroyed during the early part of pregnancy, while embedding of the ovum was in process, pregnancy always terminated. The trophic influence of the corpus luteum, carried by the vessels, is exercised on the uterus and is necessary to the insertion of the egg. The influence of the so-called false corpus luteum was also determined on non-gravid animals by burning them out, when temporary atrophy of the uterus occurred. Also, in a number of non-gravid women at operation, the corpora lutea were burned out, with the result that menstruation remained absent for one or two periods.

Daels[4] attacks Fraenkel's conclusions as being too sweeping. He denies the hypothesis of a specific function of the corpus luteum in regard to the embedding and development of the ovum. He also denies that the development of the corpus luteum, with its internal secretion, produces menstruation or that maturation of the follicle and menstruation are in a regular causal relation to each other.

While Fraenkel's conclusions are sweeping and can be maintained only by facts very difficult of proof, Daels' denial of the value of his work in its entirety is unjustified, and it may be considered proved that while maturation of the follicle and the secretory action of the corpus luteum may not cause the menses, at least menstruation is much influenced by it. We know undoubtedly that menstruation cannot occur without the ovaries and that the formation of the corpus luteum is a periodic affair, and may be of the same periodicity as menstruation. It is probable, therefore, that the corpus luteum may have an action on the uterus as a hormone, or "chemical messenger." Just as the injection of dilute mineral acid into the duodenum provokes a secretion of pancreatic juice, so the secretion of the luteum may stimulate the uterus to menstruation or aid in embedding the ovum.

Kleinhaus and Schenck[5] have brought additional evidence of the influence of the corpus luteum on fertilization. Their experiments show that, after the embedding of the ovum, destruction of the corpus luteum does not cause interference with the pregnancy; but before the ovum is embedded, termination of the pregnancy usually occurs.

INFLUENCE OF THE OVARY ON UTERINE NUTRITION

Carmichael and Marshall,[6] from their experiments on rabbits, also show the great influence of the ovary on uterine nutrition. They state that removal of the ovaries in young animals prevents the development of the uterus and Fallopian tubes. These remain in an infantile condition, but otherwise, the growth and general nutrition of the animals seems unaffected. They state that removal of the uterus in the adult animal does not give rise to any degenerative change in the ovaries if the vascular connections of the latter are intact. Bond,[7] however, claims there is evidence that there is a substance, a clear watery saline fluid, of low specific gravity, which is elaborated in the uterus between menses, which stimulates the growth of the corpora lutea, and that its absence favors overgrowth of the lutein tissue in the ovary. Holzbach,[8] however, has shown that the ovaries will persist in their function in women after removal of the uterus, and that an adequate amount of ovarian tissue, capable of function, was found in four patients, reexamined several years after the first operation of hysterectomy.

Rebaudi[9] had also shown that the removal of the ovary is prone to cause a compensatory hypertrophy in the other glands of internal secretion. He removed the ovaries in animals and found within two weeks a gradual progressive hypertrophy of the islands of Langerhans in the pancreas. He then found that when the corpora lutea alone were destroyed with the cautery, the changes occurring in the islands of Langerhans were essentially similar to those which occurred when the whole ovary was removed. He presents this as direct proof that the corpora lutea are organisms of internal secretion, and that they represent the main, if not the only, tissues of the ovary having an internal secretion.

INFLUENCE OF THE THYROID AND SUPRARENAL GLANDS ON SEXUAL CHARACTERISTICS

The influence of the thyroid amongst glands of internal secretion on the menstruation and sexual characteristics is not unknown. Disturbances of menstruation are common with exophthalmic goiter. Patients under my care have had menstrual disturbances following thyroid medication for obesity. The menstrual flow was more profuse, and in some cases, twice monthly. Galante[10] reports three cases of goiter in which there was marked change in the menstruation following galvanization of the thyroid gland.

The suprarenal gland has been shown in a forcible manner by Bullock and Sequeiria to have an influence over sexual development. Several cases in which the suprarenal was the seat of a tumor were collected, and showed that there was marked precocious sexual development in children, with development of the uterus and secondary sexual characteristics.

These evidences of the effect of the glands (other than the ovary) with an internal secretion, show that it is possible that compensatory action may occur in the absence of the direct ovarian or lutein internal secretion.

OVULATION

The time of ovulation is not, as a rule, synchronous with menstruation, but rupture of the follicle may occur at any time in the menstrual cycle. Leopold and Havano,[11] from the investigation of 95 cases at operation, found that in only 59 did ovulation occur at the same time as menstruation, so that it is possible that ovulation may occur at any time in the month. Villemin[12] states that rupture of the follicle usually occurs ten or twelve days before menstruation, and that the period after rupture corresponds to the production of the corpus luteum. These facts are interesting in determining the time at which lutein therapy should be applied each month.

It is obvious, therefore, that the consensus of opinion of experimenters and investigators is that even if the corpus luteum of the ovary is not the cause or exciting stimulus of menstruation, at least this internal secretion of lutein has a distinct influence on the production of menstruation. Therefore, it is possible that if this lutein or corpora lutea is supplied to the organism, menstruation may be influenced in some degree. With this aim, numerous investigators have obtained corpus luteum extract of the ovary from animals, with the hope of being able by opotherapy to influence menstruation and particularly, the surgical menopause.

Fraenkel reported good results with the lutein extract, and Ferroni[13] made a study of the effect of injections of corpora lutea of the ovary in animals, and reported much better results from the lutein alone than when the whole ovary was used. He believed that the effect of the injected corpora lutea was cyclic, and that there was profound metabolic change. Magalhaes[14] also reported good results with the lutein extract clinically. Many others have reported good results.

CLINICAL EXPERIMENTS

With the hope of being able to benefit some of the persistent cases of premature and surgical menopause, I have been for nearly five years experimenting clinically with a desiccated extract of corpora lutea of the ovary of cows, obtained by skinning the outside of the ovary with a sharp knife in order to obtain as much of the essential substance as possible, drying and powdering. The cow was chosen on account of the relatively large amount of lutein cells present.

I did hope to continue this study until 100 cases had been treated and the results studied, when more definite conclusions might be formed and correct therapeutic indication decided; but the publication of an article by Morley,[15] with conclusions contrary to mine, led me to report this small series of 20 cases at this time. Morley, using the same product, supplied the lutein extract to ten physicians, who returned a report of 18 cases to him. Fourteen were cases of surgical menopause, and one physician treated as many as five. It is needless to say that in a condition as obscure as the surgical menopause, as easily subject to spontaneous variations of condition, and as dependent on the individual verbal report as to the condition, this form of investigation is to be deprecated. The surgical menopause is a condition which time cures and psychotherapy may benefit. It can not be expected that definite conclusions can be drawn from one case or therapeutic indications be discovered by five. I have, therefore, been induced to report this small series with the hope that physicians may not be led to expect to find in lutein extract a universal panacea for that protean disturbance, the surgical menopause.

I have treated in all twenty cases. Ten of these cases were of scanty menstruation or approaching premature menopause. Ten were cases of surgical menopause. These cases will be discussed according to these two classes.

PREMATURE MENOPAUSE

The condition of premature menopause is one which attacks comparatively young women, between twenty and thirty-five years, and is marked by lessened menstruation, with various nervous manifestations, such as headaches, flushes and other neuroses. The condition is said by some writers not to occur before 33 years, but the establishment of the complete menopause often extends over several years, and the first effects of the condition are frequently to be observed in much younger women. It is usually associated with the lack of sexual function, as the condition is more common among spinsters and quite often dates from an illness or some definite change in nutrition or environment. This lack of sexual function in these women is curiously in consonance with the experiments of Bond who found that, in unilateral oöphorectomy in animals, the hypertrophic changes in the ovary with the formation of corpora lutea were maintained if repeated copulations were allowed.

In these ten cases of scanty menstruation, seven patients were benefited by the administration of extract of corpora lutea, gr. v. (0.3 gm.), three times daily before meals. The earlier the case was treated, the more definite seemed to be the results. The three chronic cases, in which the patients were not benefited were well-established cases with marked nervous symptoms, and did not respond to the treatment. One of the patients improved after dilatation of the cervix with the administration of the corpora lutea extract; but as it was doubtful whether the corpora lutea extract, which had been ineffectual, without the operation, was in any way responsible for the improvement, the case was classed amongst the unimproved.

[10] Galante: Ann. di elettr. med. e terapia fisica, 1909.
[11] Leopold and Ravano: Arch. f. Gynäk., 1909, lxxxviii, 3.
[12] Villemin: La Gynecologie, May, 1908.
[13] Ferroni: Ann. di. Obstet. Gynec., May, 1907.
[14] Magalhaes: Brazil med., Aug. 22, 1907.

[15] Morley: Jour. Mich. State Med. Soc., November, 1909.

The menstruation, in the seven cases of improvement, increased in amount and duration of flow. Two patients reported marked change in the character of the flow. In one very remarkable case, the patient was brought back to her normal duration of flow, of four days, while taking the lutein extract, and while untreated, menstruated two days. She was treated for three alternate months and flowed four days, while at the three alternate months untreated, she flowed two days. This seemed definite evidence of the effect of the corpora lutea in this case.

SURGICAL MENOPAUSE

Amongst the ten cases of surgical menopause, one patient was made distinctly worse, and the treatment had to be discontinued. Five were not improved and four reported some improvement. The patient who was made worse had had hysterectomy for fibroid tumor, in which an ovary had been left. The treatment was begun immediately after the operation, and caused such severe disturbance at the time of the expected menstrual period that treatment was discontinued. The patient did not suffer as markedly from the surgical menopausal symptoms after the discontinuance of the lutein extract. It is possible that the lutein excited the activity of the remaining ovary.

Another case was one of removal of both tubes and one ovary, with resection of the second, in the hope that by leaving a remnant of the ovary menstruation would continue. The remnant of the ovary remaining was about 2 by 1 cm. The menstruation did not appear for three months; after treatment for one month with lutein extract, menstruation reappeared and continued regularly thereafter. The small remnant of ovary has swollen to the size of a hen's egg, and there is pain in that region before menstruation. It is thought that the enlargement is cystic in character.

The remaining cases of surgical menopause in which the patients were benefited by the lutein extract were those in which the treatment was begun after operation, and there was no way of judging how severe the menopausal symptoms would have been without treatment.

The five patients not benefited had had hysterectomy where the menopausal neurosis was well established.

Thus, in the ten cases of surgical menopause, only one patient was definitely helped. Five were absolutely uninfluenced, and three were doubtful.

If patients with surgical menopause, in whom the uterus has been removed, are expected to be benefited by the lutein extract of the ovary, why are not those patients who have had hysterectomy, with retention of the ovaries, much benefited by the presence of these lutein-forming organs with their internal secretion? Holzbach[16] has shown that the ovary after operation retains its function, and he also states that those patients who retain a functioning ovary suffer in a more marked degree from symptoms of the surgical menopause. The majority of gynecologists now, I think, believe that the retention of the ovary after hysterectomy is ineffectual in the control of the surgical menopause, unless sufficient of the uterus remains to allow menstruation.

INTERNAL SECRETION ONLY ONE FACTOR

The manifestations of the surgical menopause are too varied and extreme to allow explanation by the mere absence of the internal secretion of the ovary. The internal secretion of the ovary is but a factor in the process of the menstrual life. It may be the hormone or "chemical messenger" which stimulates the uterus to one of its functions. Let no one expect to control these physical changes and nervous alterations of the surgical menopause by the supply of an artificial internal secretion of the ovary unless, at the same time, a new uterus to menstruate can be supplied.

But the study of this condition of surgical menopause, with its nervous and often psychopathic symptoms, is one fraught with many pitfalls. Patients are often so influenced by any treatment that it is difficult to decide which is the help. Time cures the condition and the treatment often gets the credit. I have had patients benefited by Eddyism, osteopathy, cold baths and chromium sulphate. However, in my ten cases of surgical menopause, I cannot be sure that any patient was definitely helped except that one in whom the uterus was retained. Gellhorn[17] has reported a somewhat similar case, in which menstruation, which had been absent for six months, reappeared after the administration of ovarian extract, and a regular flow ensued.

Amongst the seven cases of scanty menses or premature menopause, definite improvement resulted. In all cases there was an attempt at the same time to improve the nutrition. Three married women voluntarily stated that there was a definite increase in sexual desire. I did not question any in this regard. One patient, a woman over 45, with commencing menopause, has been under treatment for three years, with the result that the menses are still regular, and after she had been under treatment for eight months she conceived and miscarried. Her last child was born 18 years before this. She still continues the medication in the hope that she has discovered the fountain of youth.

The greatest result in every case was obtained when treatment was begun early and when the treatment was given over at least two weeks of each month. A few patients complained of nausea after meals or in the morning during the treatment.

CONCLUSIONS

The results of this study, small though it be, extending over five years, seems to indicate that the control of the surgical menopause need not be sought in the corpora lutea. Its value is in cases in which the uterus and ovaries or uterus alone are retained. Particularly is it valuable in the treatment of scanty menstruation and the premature menopause. I have treated a number of cases at the outdoor dispensary of the Kensington Hospital for women, with extract of the whole ovary, and never saw any definite results therefrom. But the lutein extract, being the essential part of the ovary, does seem to help in some degree, and should be accompanied in suitable cases, by dilatation of the uterus, with the use of the stem pessary following operation, as advised by Manson.

At least, the administration of lutein is indicated after operations on pregnant women in whom miscarriage is feared. This is particularly true in the early weeks of pregnancy, during the embedding of the ovum, as it has been shown experimentally that the corpus luteum has a definite effect under such circumstances.

THE RELATION OF STUTTERING TO AMUSIA *

E. BOSWORTH McCREADY, M.D.
PITTSBURG, PA.

I have elsewhere[1] defined *stuttering* as "a condition in which, through lack of coordination of the nervous mechanism controlling the organs of speech, which may include either excessive or deficient innervation, there is a difficulty in enunciation which may comprise either spasmodic effort without articulate sound, or frequent repetition of the same articulate sound before the utterance of the one following. With it may be associated compensatory spasm of muscles not directly involved in speech." While this definition, an adaptation of those of others, seemed satisfactory to me at the time, I have since come to realize that like those of others, it is simply an enumeration of symptoms. To my mind there has never been a satisfactory explanation of the cause of stuttering. To treat it as a neurosis, "a mental tic," is not going far enough. A neurosis it undoubtedly is, after the establishment of the compulsive idea, but calling it such does not explain why certain individuals under the influence of fright, imitation, acute disease or nasopharyngeal irritation, begin to stutter while others equally neurotic and exposed to the same influence do not.

ETIOLOGY

The observations of Scripture[2] emphasizing the fact that practically all stutterers habitually speak in a monotone, are most important, not only from the standpoint of treatment, but also as having a bearing on the etiology. That the monotonous voice is a factor in the causation of stuttering does not at all conflict with Claiborne's suggestion[3] that stuttering should be classed among the conditions caused by congenital defects in the centers controlling speech. In a paper[4] read a short time ago before the National Association for the Study and Education of Exceptional Children, I placed stuttering among the group of developmental defects caused by biologic variations in centers and commissures through which are derived perceptions of music and rhythm. If we accept the theory held by Edgren and others that the different forms of amusia are dependent on damage to special centers and commissures which are adjacent to, but not identical with, those whose damage gives rise to the corresponding forms of speech defect, we must assume that an auditory center for tones will correspond with the auditory word-center, a kinesthetic tone-center with the kinesthetic speech-center and a visual center for notes with the visual word-center.

According to Bastian,[5] "the existence of tone-deafness as an isolated and inherent defect is probably far from rare." There are persons who are incapable of discriminating between the two notes of an octave and who notwithstanding the most frequent opportunities of hearing music remain quite incapable of distinguishing one tune from another. Variations in the kinesthetic center or its commissures would account for the inability of some individuals to "carry a tune." There are some persons who, while possessing a "musical ear," are still unable to reproduce what they have heard. I have, on a previous occasion,[4] drawn attention to the connection between amblymusia and idioglossia.

Nature is all curves and harmony. We are constantly receiving, through the special senses, impressions suggestive of modulation, inflection and consonance. On the visual center are registered impressions of form derived from the contour of hills and sky, from the flight of birds, the waving of the branches of trees, the falling of leaves; on the auditory center, from the sound of running water, the soughing of the wind, the rustle of leaves, the songs of birds; on the centers controlling the sense of touch are registered the impressions received from the handling of smooth and rounded objects, and on the general kinesthetic centers the impressions of rhythmical movements made in walking, running, bending, climbing, breathing, etc.

It seems therefore not unreasonable to suppose that these various impressions, registered as they are, in areas of which the centers concerned in speech are a part, have much to do not only with its development, but also with the proper control of the nervous mechanism of the speech-forming organs. To state more clearly, it would appear that impressions of modulation, inflection, consonance and rhythm are registered on special centers which are a part of the general visual, auditory and kinesthetic areas, and that each of these beside being in direct relationship with the word-center of the particular area of which it is a part, is also in commissural relationship with the corresponding centers of other areas.

I further believe that the monotonous voice of the stutterer is the result of a biologic variation in one of the music centers or its commissures, most likely, in the kinesthetic center or the commissure between it and the auditory music-center. It may be held that not all those with unmelodious voices stutter. While they may not do so habitually I believe it will be found that they will sometimes stutter, especially when laboring under strong emotion or fatigue, or when in poor physical condition. The child does not stutter from the time he begins to speak but if he is the possessor of a monotonous voice he will do so as soon as he is subjected to one of the exciting causes mentioned above or to reflex irritation from any source, be it eye-strain, phimosis, adenoids, or worms. The compulsive idea then becomes fixed. I have been asked why, if stuttering bears the relation to amusia which I claim it does, many stutterers are able to sing. I think this fact can be explained on the same basis that Dercum explains the same ability in some cases of aphasia. He says:[6] "The curious instance of the singing aphasics can only be met by a similar explanation (reenforcement). For instance, I had under my care some years ago a Broca aphasic, whose speech was limited to "yes," "no" and a few brief expletives. He could, however, sing—among other things—"Auld Lang Syne," carrying the air well and enunciating each word clearly. No other explanation, it would seem to me, than that of reenforcement overcoming inhibition can apply in such a case."

METHODS OF TREATMENT

If we accept the theory that stuttering is due to biologic variations in centers which are a part of or are closely associated with centers making up the zone of language, the reason for the success and failure of many empirical methods of treatment of this disease are apparent. Practically every method that has been suggested is based both on distraction from the compulsive idea and on oft-repeated impressions of correct speaking. In other words, the patient receives from his instructor auditory and visual impressions of properly inflected and articulated words, and further than this by repetition educates his own brain cells, assisting them to perform their proper function in unison with other cells, or by forcing the opposite hemisphere to supply a center similar to that which is imperfectly developed. This is done principally through the glosso-kinesthetic center acting in conjunction with the various music-centers. Failure to cure and relapse after apparent cure are due to development of the glosso-kinesthetic center, with failure to bring about functional relationship with the music-centers. The "melody cure" advocated by Dr. Scripture fulfills all the indications necessary for a complete cure beyond danger of relapse. It should, however, be persisted in until every assurance is felt that the centers controlling melodious speech have assumed the necessary state of activity. Every effort should be made to imprint musical impressions through every available avenue, and to allow every possible opportunity for their expression. It is a well-known fact that music, dancing, rhythmical movements, drawing, etc., are great aids in the development of speech and of general cerebral activity in the backward and feebleminded.

[6] Dercum, F. X.: The Interpretation of Aphasia, Am. Jour. Med. Sc., November, 1909.

Another great aid in the treatment of this class of cases is the reversal of dexterity as advocated by Claiborne.[3] It is generally conceded that in right-handed individuals the complicated mechanism of speech is controlled by the zone of language in the left cerebral hemisphere.

"It must needs be admitted that there is a general auditory, a general visual area, and a general kinesthetic area in the right hemisphere, and that incoming stimuli make on it an impression similar to that which they do on the so-called "educated" hemisphere. These impressions are bilateral in reception, but unilateral in interpretation. This unity of interpretation is determined by commissural fibers of the corpus callosum. Now the same factors that determine right-handedness determine also that the left hemisphere shall be the executive speech side, but the elementary work is done on both sides."[7]

Now as Claiborne says,[3] "It is in the highest degree unlikely that a congenital defect should occur on both sides of the brain and in the same place."

In a biologic variation in brain-centers not so much can be expected from restitution of non-functionating cells as from a process of functional compensation, brought about by the undamaged hemisphere gradually taking on new or greatly developed functions.

General kinesthetic impressions have a decided influence on the development of the speech-centers as is proved by the marked improvement shown by cerebral hemiplegics after tenotomy. The more frequent and dexterous use of the muscles of one side would, therefore, assist materially in the development of the speech-centers of the opposite hemisphere.

I have reported two cases of congenital word-blindness in boys both of whom were originally right-handed who learned to read after they had become proficient in the use of the left hand together with special training. In one,[8] a youth of twenty, who stuttered very badly, I noticed a decided improvement in speech soon after he had begun to use the left hand. In fact, although I had had him under treatment for several months I had been unable to get him to speak with any degree of inflection, until after he had begun the use of the left hand. His subsequent improvement in speech was very rapid. It has been my custom for the past year, in addition to giving all my stuttering patients exercises directed toward correcting their various defects of speech, to advise them to use, when right-handed, the left hand in preference to the right. I am fully satisfied of the value of this procedure, and while I do not believe that the reversal of dexterity will in itself correct stuttering or any other developmental defect due to a biologic variation in special cerebral centers, I do believe that it will prove itself a very valuable aid when taken in conjunction with other approved methods of treatment.

CONCLUSIONS

While incapable of proof, it is reasonable to suppose:

1. That the defective use of the muscles of inspiration, expiration, and of the lips, tongue and throat, resulting in stuttering is the "result of imperfect coordination, caused by disconnected and erratic discharges from the cortex."

2. That this incoordination is between the nervous mechanism controlling the acts of vocalization and articulation and the centers having for their function the appreciation and expression of melody and harmony, and is due to a biologic variation in such a center or its commissures.

3. That the cure of stuttering is only accomplished by a process of compensation brought about by the education of cells previously non-functionating, and by forcing the opposite hemisphere to supply a center similar to that which is imperfectly developed. To this end the reversal of dexterity would seem to be a reasonable procedure.

THE TREATMENT OF FURUNCULOSIS

JOHN T. BOWEN, M.D.
Edward Wigglesworth Professor of Dermatology, Harvard University
BOSTON

By furunculosis is generally meant the repeated outbreak of furuncles either singly or in numbers, extending over a period varying from several weeks to many months and even years.

As to the etiology of this condition the last word has by no means been said. We know that a furuncle is usually, if not always, caused by the infection of a hair or sebaceous follicle with the *Staphylococcus pyogenes aureus*. We know that furuncles are propagated by auto-inoculation, the new lesion being produced by infection from an old one. We know that diabetes, debility, and albuminuria are conditions that may increase the susceptibility of the individual to infection in this way. We know that the development of furuncles is facilitated by external irritants to the skin, of whatever nature. Apart from the above etiologic factors which are present in only a small number of instances, we do not know what it is that produces in the majority of the cases this peculiar susceptibility to inoculation of the follicles with the staphylococcus.

[7] Collins, Joseph: Ref. Handb. Med. Sc., i, 419.

[8] Congenital Word-Blindness as a Cause of Backwardness in School Children: Report of a Case Associated with Stuttering, Pennsylvania Med. Jour., January, 1910.

With regard to the treatment of individual furuncles, many and various are the methods resorted to. It is not my purpose to enlarge on these procedures, or their relative efficiency. Suffice it to say that I do not believe that early incision shortens the duration; nor do I believe that poulticing is to be recommended, except in rare instances, as it is contrary to aseptic principles.

In calling attention to a method of treating the skin of those afflicted with furunculosis that has proved universally effective in a large number of cases during the last fifteen years, I do not wish to detract in the slightest degree from the vaccine method. I have seen the most brilliant results from the latter treatment, remarkable for the quickness with which relief was afforded. I know of no method that compares with it, in a certain number of cases. Nevertheless, it is not successful in all cases, and I have happened to have a considerable number of cases that had been treated by the vaccine method by most competent people without any success, that have yielded to the local treatment that I am about to describe.

No originality is claimed for this treatment. Some of its principles were suggested to me many years ago by Dr. James C. White. In many of the text-books some of its essentials are referred to. The principle is simply to keep the skin as far as possible sterile.

In the first place the patient is directed to wash the whole body with warm water and soap in the morning and at night. This part of the treatment I regard as most essential. It is true that when the furuncles have been confined to the neck it may be sufficient to wash only the upper half of the body, but it is not so thorough a procedure. After this thorough washing of the whole body with soap and water, and the skin has been dried, the whole surface is then bathed with a saturated solution of boracic acid in water. Other antiseptic solutions may be used, as corrosive sublimate, but I prefer the boracic acid solution, and regard it as most effective. The skin is allowed to dry without wiping, and then the individual furuncles are dressed with the following ointment spread on cotton or linen, and bound on if possible.

℞.	gm.	
Boracic acid	4	or āā ʒi
Precipitated sulphur	4	
Carbolized petrolatum	32	℥i

Early opening of the individual lesions is not advised, incision being resorted to only after the lesions have become very painful and mature.

Another important point is to have all the clothing that comes next to the skin changed daily. It is unquestionably true that the germs are often retained in and reinoculated from the collars and underclothing.

It is not to be understood that in applying this treatment, no thought should be given to the improvement of the general condition by internal and hygienic measures. On the contrary, everything should be done on general therapeutic principles to promote the well-being of the patient.

It is not claimed that this method often accomplishes the brilliant results that are attained by the vaccine method. Nevertheless, it has rarely failed when carried out with care and patience, and has, in my experience, frequently succeeded where the vaccine treatment has failed. I am convinced that a careful trial of it will prove that the statement made at the Sixth International Dermatological Congress by a distinguished foreign visitor, that the opsonic treatment is the only form of treatment for general furunculosis which is in the slightest degree reliable, must be modified considerably when the results obtained from this method of sterilization are recognized.

A MODIFIED EXTRACTOR FOR THE REMOVAL OF VARICOSE VEINS OF THE LEG

W. WAYNE BABCOCK, M.D.

PHILADELPHIA

This instrument is a modification of the simple device I described in 1907,[1] for the removal of varicose veins of the leg. The larger acorn tip of the instrument has been increased in size and its surface toward the shaft of the instrument so cupped as to catch the wall of the vein and prevent its inversion and slipping over the end of the instrument. In using the instrument the vein is exposed either at the upper or lower termination of the segment to be removed. With the internal saphenous vein, which is most frequently extirpated, the exposure is made either just below the saphenous opening in the thigh or on the inside of the calf of the leg.

The vein is exposed, grasped with hemostatic forceps, incised and the smaller end of the instrument slipped into the lumen of the vein for the required distance or until some obstruction is encountered. With strong silk the wall of the vein is firmly tied to the shaft of the instrument, the vein ligated, divided between the point of ligature and the instrument, and the hemostatic forceps removed. The smaller bulbous tip of the instrument, which may be seen and felt beneath the skin, is now exposed by incising the overlying skin and wall of the vein, grasped, and by firm traction combined with a series of short jerks the instrument with the affixed segment of vein is extracted. The wall of the vein slips to the other end of the instrument and becomes firmly pleated in a small fusiform mass against the concavity of larger tip of the instrument. The venous branches are torn off from one to several centimeters distant from the main trunk and do not give rise to troublesome hemorrhage. The procedure may be repeated with other varicose veins as desired. Finally the short incisions are closed. The instrument may be introduced into the vein from above downward or from below upward whichever is the more convenient in the particular case. By this instrument one may often remove, through two incisions, one measuring about one inch or less and the other one-half inch in length, twenty or more inches of vein within a very few minutes.

A modified extractor for the removal of varicose veins.

The instrument shown in the illustration is jointed; the joint is, however, not an indispensable feature of the device.

2033 Walnut Street.

Special Article

TYPHOID FEVER IN MILWAUKEE AND THE WATER SUPPLY

[*By Our Special Commissioner*]

Typhoid fever seems always to have prevailed more or less extensively in Milwaukee. The following table gives the total number of deaths from this disease, and the corresponding typhoid death rates for the years 1869 to 1909 inclusive.

TABLE 1.—TYPHOID DEATH-RATES, MILWAUKEE, 1869-1910

Year.	Population.*	No. Deaths.†	Deaths Per 100,000 Population.‡
1869	68,820	44	61.0
1870	71,440	58	81.2
1871	75,854	35	46.2
1872	80,269	70	87.2
1873	84,684	49	57.9
1874	89,098	69	77.4
1875	95,513	25	26.2
1876	97,927	36	36.7
1877	102,341	36	35.2
1878	106,755	25	23.4
1879	111,169	32	28.8
1880	115,587	43	37.2
1881	124,475	59	47.4
1882	133,363	42	31.5
1883	142,251	35	24.6
1884	151,139	47	31.1
1885	160,027	44	27.5
1886	168,915	51	30.2
1887	177,803	55	30.9
1888	186,691	78	41.8
1889	195,579	55	28.1
1890	204,468	83	40.6
1891	212,553	71	33.4
1892	220,638	66	29.9
1893	228,720	80	34.9
1894	236,808	60	25.3
1895	244,893	63	25.7
1896	252,978	46	18.2
1897	261,063	31	11.8
1898	269,148	46	17.1
1899	277,233	47	17.1
1900	285,315	59	16.9
1901	290,494	63	21.7
1902	295,673	48	15.1
1903	300,852	54	16.8
1904	306,031	43	13.6
1905	311,210	68	22.9
1906	316,989	98	30.5
1907	322,168	89	25.7
1908	327,347	55	16.8
1909	332,526	78	23.4
1910	337,117	..	....

* Population of 1870, 1880, 1890, 1900, U. S. Census; 1910, U. S. Census Bureau estimate. Intervening years calculated by "arithmetical" method (Twelfth Census Bull. No. 135).

† Number of typhoid deaths recorded in Reports of Health Department.

‡ Rates computed directly from populations and typhoid deaths given in this paper.

By five-year periods the rates are as follows:

TABLE 2.—AVERAGE TYPHOID DEATH-RATES BY 5-YEAR PERIODS

1870-4	70.0	1890-4	32.8
1875-9	30.1	1895-9	17.4
1880-4	34.4	1900-4	17.3
1885-9	31.7	1905-9	24.0

COMPARISON WITH OTHER CITIES

From these data it appears that, in comparison with other American cities of similar rank, the average typhoid death rate in Milwaukee in recent years has not been remarkably high. During 1898-1908, it averaged 19.7. This figure would cause it to be placed eleventh in point of typhoid fatality among American cities of over 100,000 population (census of 1900). Ten cities had a lower average typhoid death rate than Milwaukee during this period and 27 a higher.[1] At the same time a death rate of 19.7 cannot be regarded as remarkably low. The typhoid rate of German cities with a population of over 15,000 (a total population of 19,127,096) averaged in 1902-4 only 6.7. The city of Madison, situated less than 100 miles from Milwaukee, reported an average typhoid rate of 5.8 for the years 1900-8. The average typhoid rate in Chicago for six years, 1904-9, was 16.7; in Milwaukee for the same period, 22. Milwaukee itself is in a region of the country having comparatively little typhoid fever. The typhoid rate for the whole state of Wisconsin—a registration state—for 1908 was 13.9, only Rhode Island among the registration states having a lower rate (12.9).[2]

WATER SUPPLY

The water supply[3] of Milwaukee was first obtained from springs and wells, and from the three streams—now open sewers—passing through the town. A town pump was in existence in City Hall Square as late as 1875. In 1870-71 authority was given the city by the state legislature to issue water works bonds; in 1871 a board of water commissioners was created. The supply was at first taken from Lake Michigan through a 36-inch cast iron pipe laid in the bottom of the lake, extending 2,100 feet from the shore to a crib. The pumps on the lake shore were started Sept. 14, 1874, but for about a year before this date (Nov. 3, 1873—Sept. 14, 1874) water from the Milwaukee River was pumped into the reservoir as a temporary supply for the fire department.

The depth of water at the original intake was eighteen feet, the inflow being eight feet below the surface. This served as the source of water supply up to 1895, when a new intake was completed. The old intake is still connected with the works as a reserve in case of emergency, but is said not to have been used since the above date.

The present intake consists of a brick tunnel, seven and one-half feet inside diameter, extending 3,200 feet to a crib, from which point two lines of cast iron pipe, five feet in diameter, extend 5,000 feet to submerged cribs in sixty feet of water. The inflow is situated about fifteen feet above the lake bottom. The total length of the intake is about 8,200 feet.

From the pumping station on the lake shore which has a daily pumping capacity of 86,000,000 gallons, the water is pumped to a distributing reservoir, with a capacity of 21,000,000 gallons, and to two high service stations.

The sewage of Milwaukee passes for the most part into the three rivers which intersect the city, the Milwaukee river, the Menomonee river, and the Kinnickinnic river. (See diagram.) A slow current sets toward the harbor mouth. The stench arising from these open sewers has caused flushing of the streams to be undertaken as a remedial measure. Two flushing tunnels have been constructed; one in connection with the Milwaukee river; the other, completed in 1907, in connection with the Kinnickinnic river. In 1909 the Milwaukee River Flushing Works displaced over *fifteen* billion cubic feet, the *Kinnickinnic river* works over twelve billion. The effect is of course to hasten the flow toward the lake. In addition to the sewage entering the lake from this source, an intercepting sewer runs to the north end of Jones Island, just south of the harbor, and at this point fresh, crude sewage is pumped into the lake at a rate of over 55,000,000 gallons daily. (See diagram). The point where the sewage-laden river together with the pumped sewage, enters the lake is about three and one-half miles southwest of the water intake. *No city sewers* empty into the lake north of the harbor mouth. Some drainage from summer resorts and isolated houses enters the lake at various points north of the water intake, but the volume of such drainage appears to be very small.

---

[1] For data see Taylor: Engineering News, April 21, 1910.

[2] Bureau of Census Mortality Statistics, 1908.

[3] The data here set forth are chiefly taken from a historical description by Mr. Thomas McMillan, chief engineer of the pumping station, kindly furnished by Dr. W. C. Rucker.

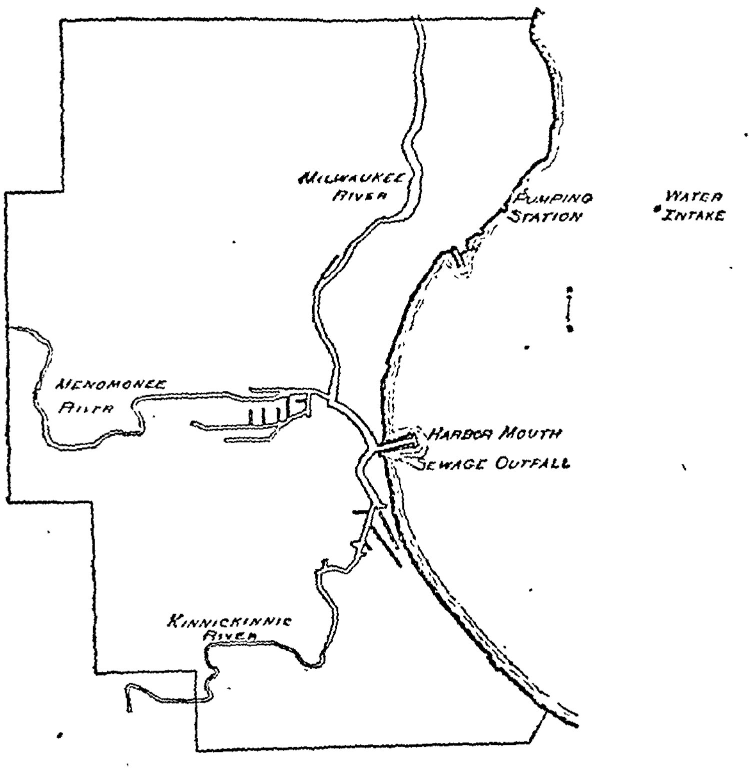

Diagram showing sewage outfalls and water intake, Milwaukee, Wis.

The possibility that some of the Milwaukee sewage may drift north and mingle with the water drawn at the intake is one that must be ever reckoned with. It has been sometimes held that on this—the west—side of Lake Michigan, the general direction of the lake currents is from north to south, but it is plain that there can be no absolute constancy in this respect. The direction and force of the wind, the fluctuation in lake levels and temperature, and other factors must to a greater or less extent affect both the surface drift and the deeper lake currents. Major W. V. Judson, of the United States Corps of Engineers, in a recent paper[4] on "Currents in Lake Michigan," expresses very forcibly this view of the irregularity of Lake Michigan currents.

> We do *know*, and perhaps it is enough for the purposes of this *commission*, that occasionally currents of considerable velocity, say several miles per hour, may be expected to arrive from almost any direction at any point reasonably near either shore of the lake. It is therefore apparent that in the general case if the waters of the lake are polluted by the discharge into it of large quantities of sewage, then practicable localities in the lake, even twenty to thirty miles distant from the point of entrance of the sewage, are not safe places from which to derive water for domestic use.

A similar view has been well expressed by Amyot.[5]

> In the neighborhood of our cities it has frequently been observed that with favoring winds streams of unchanged sewage, like the Gulf Stream, wend their way out from shore as much as three or four miles. The winds are very inconstant in direction in these lakes, so that these streams may be easily blown up or down shore. Winds up or down the lake, *lasting any length of time, cause piling up of the water.* When this finds its *level, currents of inconstant direction* start up or down the lake.

Even a rather deep intake under these conditions is exposed to pollution, since a wind blowing in-shore may cause a heaping up of contaminated surface water, which then flows outward in a deep countercurrent. Several physical agents may be concerned in bringing about a pollution of the water supply, and it is hardly to be anticipated *that as a rule meteorologic* conditions will *show* an *unmistakable* relation with *typhoid fever outbreaks.*

Apart from the probability, on these grounds, that at times Milwaukee sewage must to a greater or less extent enter the water supply, there is direct analytical evidence that such pollution actually occurs. Dr. G. A. Bading, *former* commissioner of health, in a communication to the city council in August, 1908, wrote: ". . . . analysis, both chemical and bacteriologic, made at regular intervals, unquestionably demonstrates the presence of contamination." The report of Dr. G. C. Ruhland,[6] city bacteriologist, included in Dr. *Bading's* paper, states that "I have repeatedly found undoubted colon contamination."

REASONS FOR BELIEVING TYPHOID FEVER IN MILWAUKEE IN PART WATER BORNE

As already pointed out, *the typhoid rate in* Milwaukee ranges in general somewhat higher than that of neighboring cities (Madison, Chicago) possessing a pure or slightly polluted water supply. Although the state of Wisconsin contains some cities with a very high typhoid rate (1908: Eau Claire, 51.4; Kenosha, 58.2; Sheboygan, 97.3), the typhoid rate *for the state* as a whole was in 1908 considerably below the Milwaukee average. In a word, the general conditions of the region, wherever special water pollution does not exist, are accompanied by a lower typhoid rate than that occurring in Milwaukee.

At first the use of the lake water was followed by a sharp reduction in the amount of typhoid fever. The first year of use of the public supply (1875) was marked by a typhoid rate less than one-half the preceding five-year average. The lake water itself, however, was not guiltless as shown by further developments. Examination of the annual typhoid rate (Table 1) shows a period of irregular and rather high mortality up to 1895. In the next five-year period, a much lower mortality is observed. It must be noted that in 1895 the new water tunnel was completed, thus shifting the intake about

6,000 feet farther out into the lake. It is a justifiable conclusion that the purer water thus obtained was responsible for the lowering of the typhoid death rate. The influence of the water supply in producing typhoid fever is here shown in a striking way.

For a list of typhoid deaths 1890 to 1910, tabulated by months (Table 3), we are indebted to Dr. W. C. Rucker, Health Commissioner of Milwaukee. This table shows, in addition to the regular autumnal incidence, several periods of unusually high mortality. These may be noted especially in December, 1904 and January, 1905; in May, 1905; in March-April, 1906; in December, 1906, and January-February, 1907; and in March-April, 1909. Now this tendency toward excessive prevalence in winter and spring is precisely similar to what was observed in Chicago[7] prior to the opening of the Chicago Drainage Canal. Attention may especially be directed to the spring and winter epidemics of 1890, 1891, 1892, and 1896 in Chicago. At the time these occurred the situation in that city as regards water supply was substantially identical with that now existing in Milwaukee, namely a supply derived from Lake Michigan without purification and exposed to pollution with considerable amounts of raw sewage at irregular and varying intervals. There is also the same general history of typhoid fever in the two cities. Extension of the water intake in Chicago was as a rule followed by a period of relative freedom, and then with the continued growth of the city the disease again became prevalent.

There is evidence that the real nature of the situation has for some time been recognized by the health authorities of Milwaukee. The commissioner of health in 1899 (Dr. F. M. Schulz) wrote in the twenty-third annual report:

> Although the city at present possesses a good water supply, notwithstanding the fact that we are discharging about 60,000,000 gallons of sewage into the lake daily, it is only a question of time when, through the natural increase and growth of the city, the amount of sewage swept out into the lake will assume such proportions as to affect seriously the potability of our water.

And again in 1904 (28th Annual Report):

> While the supply of our city is under ordinary circumstances very satisfactory, every southerly and southeasterly wind would seem to carry a certain amount of contamination from the harbor dangerously near the intake, and this may sometime easily threaten the purity of the water supply.

In 1905 a definite outbreak of the disease was attributed to water pollution:

> A large number of cases of intestinal infection and a considerable number of cases of typhoid fever occurring during the month of May [Table 3] led to exhaustive chemical and bacteriologic examination of the water. . . . It is supposed that the heavy rains which occurred during April carried a large quantity of sewage into the lake. . . . In conjunction with this . . . we had for some weeks almost constantly southwest winds which facilitated the transfer of this sewage to the intake.

The bacterial examination of the water has shown unmistakable, although not as a rule extreme pollution, as stated by Dr. Ruhland, city bacteriologist, in the reports just cited.

From all these converging lines of evidence, environmental, epidemiologic, and analytical, there can be little doubt that at least a considerable proportion of the typhoid fever occurring in Milwaukee during a long series of years must be attributed to a polluted public water supply.

OTHER POSSIBLE SOURCES OF INFECTION

No one can suppose that in a city the size of Milwaukee water is the only medium of infection. In Washington, D. C., the typhoid rate averaged about 40 in the years 1906-8, and there is no reason to suppose that the public water supply played a large part, if any, in the spread of the infection. It is possible that some at present unknown mode of spread in both Washington and Milwaukee is responsible for the greater part of the typhoid fever cases, but until other possibilities are exhausted we are not justified in resorting to this assumption. Well-known possible sources of infection are milk-supply, contact with typhoid cases and with typhoid bacillus carriers, raw fruit and vegetables, and fly contamination.

These possibilities may be briefly considered, although it is plain that prolonged and intensive investigation of the local conditions would be necessary before a decided opinion could be expressed as to the weight to be given the several factors. Inspection of Table 3 shows that during the last twenty years typhoid fever has occurred frequently at times of year when the agency of the house fly could be excluded. The present outbreak furnishes a case in point. The large amount of typhoid

[*] By kindness of the Weather Bureau.

fever in the winter and spring of 1910 could not have been due to fly infection.

We are, however, told by officials of the health department that there are several hundred open privies still in use in the more thinly settled parts of the city and that many hundreds have been abolished during the last three years. The present extensive distribution of cases will render the privies in the coming summer more than ever a source of danger from fly contamination. In the past fly contamination has doubtless played a part in Milwaukee as elsewhere, but to just what extent cannot be determined by any available data. The seasonal and geographic distribution of cases would not seem to justify assigning it a prominent position.

Contact infection in like manner has doubtless occurred and is now occurring in Milwaukee but there seems no reason for attributing to it a larger share in causation than should be assigned to it in the neighboring city of Chicago where, during the past six years, the typhoid fever rate has been considerably lower than in Milwaukee (Chicago, 16.7, Milwaukee 22).

In regard to possible contamination of fruits and vegetables, it may be remembered that this is especially liable to occur when the contents of privy vaults are used by market gardeners. We have no means of knowing the extent to which such a practice prevails on the truck farms in the neighborhood of Milwaukee, but the distribution of cases in time and space does not suggest that this can be one of the main factors.

The milk supply of Milwaukee, as already indicated, does not come from a region where there is a particularly high typhoid mortality. In the present outbreak there is not the disproportionate mortality among children that usually accompanies milk-borne epidemics. The records of the health department show that in the present outbreak there is no special incidence of the disease among particular milk-routes. There are no data available for determining the relative amount of milk-borne infection in Milwaukee at an earlier period.

THE PRESENT SITUATION

In the current year, 1910, there has been an unusual amount of typhoid fever in Milwaukee. This is shown by the unanimous testimony of physicians, by the fact that there are many more typhoid cases than usual in the hospitals, and by the necessity that has arisen for bringing in additional trained nurses from neighboring cities. On July 1 an appeal was issued by the Associate Charities of Milwaukee for funds to continue the work of the organization. In this appeal it is stated that "The Associated Charities are at this time almost entirely without working funds. The typhoid fever epidemic is mainly responsible for this unusual state of affairs. In the month of June just past the Associated Charities cared for 350 cases more than ever before in the history of the organization, more than in the panic years, and three times more than last year. Of these, 90 cases were illness, mostly typhoid fever."

The records of the health department show the extent to which the disease has prevailed (Table 4)).

A map has been prepared by the health department, showing the distribution of cases throughout the city. The poorer sections do not seem to have suffered disproportionately. The "spot map" furthermore does not reveal the existence of a number of scattered centers, but rather a uniform distribution, such as would be expected if a common factor such as a public water supply were concerned in the causation. There is nothing in the distribution of cases, so far as has been disclosed, to conflict with the hypothesis that the present rather extensive outbreak owes its origin to the lake water. On the other hand, no explanation for the particularly severe incidence of the disease at the present time has been advanced. The amount of sewage discharged into the lake has not materially increased during the last three years. Comparison of the figures of the monthly rainfall recorded by the weather bureau (Table 5) does not throw much light on the problem. It is tempting to suppose that an unusually heavy rainfall such as occurred in December, 1909 (1.44 in. above average) and April, 1910 (0.78 in. above average) may have produced a particularly extreme water pollution, but on the other hand the much more excessive April rainfall of 1909 (4.39 in. above average) was not followed by unusual typhoid prevalence. From data already given it is plain that not only rainfall but wind direction must influence profoundly the extent of contamination. It is, therefore, perhaps useless to attempt to trace any connection with meteorologic conditions where a concurrence of several factors is necessary to bring about the result and when, given exactly the right conditions, a few hours may be sufficient to produce a serious infection of the water supply. At the same time it is difficult to avoid the suspicion that a heavy rainfall such as occurred in November, 1891, was one of the factors in producing the outbreak of typhoid in the following December and January.

REMEDIAL MEASURES

When the gravity of the existing situation became manifest, warnings to boil the drinking water were issued by the health department and leaflets of instruction were printed in several languages and distributed broadcast. On June 20 a temporary plant for chlorination of the water was put in operation near the pumping station. This was being operated sixteen hours a day on July 1. The analytical results of this procedure are said to be excellent, the tap-water showing marked bacterial improvement.

It is significant that the whole problem of sewage disposal is now and for some time has been under advisement. As the result of a communication to the Common Council by Dr. Bading in 1908 an expert sewage commission, consisting of the well-known sanitary engineers, Messrs. J. W. Alvord, G. C. Whipple, and H P. Eddy, was appointed to devise plans for a system of sewage disposal. This commission has not yet completed its investigation, but a report is expected in the near future. It is thus evident that the whole situation in Milwaukee is on the way to speedy betterment.

SUMMARY AND CONCLUSIONS

The history of typhoid fever in Milwaukee shows first a period of very excessive prevalence, (1869-1874). The introduction of a public water supply improved conditions greatly. This usually happens when shallow wells are abandoned for a large body of water. In spite of the improvement, however, the typhoid rate remained excessively high (over 30) for a period of 20 years. Then in 1895 the water intake was extended 6,000 feet further out into the lake. The result was an immediate drop in the typhoid rate to about one-half. Slowly, however, the growth of the city asserted itself by an increasing volume of sewage poured into the lake and a consequent increased contamination of the water supply. In the present year (1910) the typhoid rate promises to be as high as before the extension of the water intake. No other probable source of a large amount of typhoid fever has been discovered and there can be little if any doubt that the public water supply is responsible for the present outbreak. When millions of gallons of sewage are discharged into a lake a few miles from a water intake it needs no divining rod to detect the possibilities of danger. No fact in epidemiology is more clearly established than that sewage-contaminated drinking-water is a cause of typhoid.

A CASE OF RETROGRADE PUBERTY, IMPOTENCE AND DIABETES INSIPIDUS, RELIEVED BY SUPRARENAL CORTEX

WILLIAM T. BELFIELD, M.D.
CHICAGO

History.—In 1897, H., aged 27, married, developed (1) polyuria without sugar, 120 to 150 ounces daily; (2) retrograde puberty; i. e., atrophy of testes, disappearance of beard, pubic and axillary hair, the scalp hair remaining luxuriant. The condition, called diabetes insipidus by the physicians consulted, had existed for twelve years, when, in 1909, the patient was referred to me.

Diagnosis.—The polyuria and retrograde puberty suggested an excess of pituitary secretion. As an *x*-ray picture of the pituitary region by Dr. Reichmann revealed nothing abnormal, the pituitary excess was assumed to be not absolute, but relative, possibly from deficient secretion by the adrenal cortex.

Treatment.—After thyroid substance, and later adrenalin (which is derived from the adrenal medulla only), had proved futile, he was given daily four grains of suprarenal substance, containing cortex as well as medulla.

Result.—Improvement was prompt and distinct; after four months of this medication his daily urine is only one-half the average during twelve years; beard and body hair have grown markedly; the testes have doubled in size, and coitus has been practiced several times, after twelve years of absolute impotence. In short, he is exhibiting puberty a second time.

As two other cases of retrograde puberty—a type seemingly hitherto unrecognized—have come to my notice, possibly they are not rare.

100 State Street.

SYPHILIS IN INSANITY AS DETERMINED BY THE WASSERMANN REACTION*

C. B. ENSOR, M.D.
BALTIMORE

Of 262 male patients from Mt. Hope Retreat, tested by the Wassermann method, a positive reaction was obtained in 58, or in 22 per cent. of the total male population. Of the 262 patients, a history of syphilis was given in only 3 per cent. of the total, and only 14 per cent. of the patients showing a positive reaction admitted having syphilis, though most of them acknowledged exposure, and having had gonorrhea; 86 per cent. of the patients with positive reactions thus denied having had syphilis at any time. On the other hand, a history of syphilis was admitted where the reaction was negative in 2.6 per cent. of the total admissions. Of the 58 positive cases, 69 per cent. of the patients have been in the institution one year and under, 12 per cent. have been there two years, and 19 per cent. have been there three years and over.

We classify the positive cases as follows:

	PER CENT.
Chronic alcoholic insanity	15.5
Dementia præcox	18.9
Dementia paralytica	17.2
Maniac depressive insanity	15.5
Organic dementia	20.4
Paranoia	3.4
Involutional insanity	6.8
Constitutional insanity	1.7

Of 21 patients from other sources 16 were paretics with a positive reaction in all, and of 27 cases of paresis collected from all sources, 96 per cent. of patients gave a positive reaction. Of 7 cases of tabes 83 per cent. of reactions were positive, and of 5 cases of cerebral syphilis 4 were positive, while in the only negative case the patient had been receiving mercurial injections for the previous six months.

PRELIMINARY NOTE ON THE ACTION OF EHRLICH'S SUBSTANCE 606 ON SPIROCHÆTA PERTENUIS IN ANIMALS†

HENRY J. NICHOLS, M.D.
Captain, Medical Corps, U. S. Army
NEW YORK

The usual treatment of yaws with potassium iodid or mercury is very tedious, but the encouraging results already obtained in the treatment of other diseases due to spirochetes, namely, syphilis, relapsing fever and fowl spirillosis, by a single injection of Ehrlich's substance "606"[1] suggest that his principle of "therapia magna sterilisans" may be applied also to yaws.

As a preliminary to the use of any new drug on man, its trial on animals is, if possible, of course, strongly indicated on many grounds. Up to the present, the only animal experimentally infected with yaws has been the monkey, various species of which have been infected by Castellani in Ceylon, Ashburn and Craig in the Philippines and Neisser, Halberstadter and Bauerman in Java. A definite lesion results from inoculation, but apparently the reaction is rather superficial, as is indicated by a late weak complement fixation reaction and a relative scarcity of spirochetes.

Recently, I have succeeded in infecting rabbits in the testicle with the spirochetes of yaws and this lesion is an excellent guide to treatment, as the spirochetes are present in myriads in pure culture, the serum reaction is prompt and strong and the organ can easily be removed and examined. Rabbits, also, are, of course, easier to obtain and to handle than monkeys.

The spirochetes came from a colored soldier returning from the Philippines who had a well-marked case of yaws with three separate general eruptions.[2]

A monkey was first infected on the eyebrow and transfers were then made of the serum of the monkey's yaw to rabbits' testicles. Three rabbits of the first generation became infected in an average of forty-one days and the infection was then carried on from rabbit to rabbit. The spirochetes are now in the seventh generation in the rabbit and the incubation period has fallen to about twelve days. A detailed account of this work will appear in the *Journal of Experimental Medicine* in a short time.

The lesion seems to differ only in degree from a syphiloma of the rabbit's testicle and consists of an edematous tumor in the testicle or epididymis, varying in size from that of a pea to that of an olive. On puncture with a capillary pipette and examination of a drop of the serum with the dark-field microscope a brilliant picture is obtained. Levaditi stained sections are equally striking. The lesion persists four to six weeks and the Wassermann reaction occurs in the first or second week. The general health of the animals is not noticeably affected.

Ehrlich's "606" is dichlor-dioxy-diamido-arseno-phenol; it is a golden yellow powder put up in vacuum tubes, and is given in the form of a disodium salt freshly prepared before each injection. This substance has been built up with the idea that it shall have a selective action for spirochetes and thus open the way to sterilize the tissues by a single adequate dose. Up to the present, no toxic effects of the drug itself have been observed[3]. A quantity of the material has been recently sent to the Rockefeller Institute by Professor Ehrlich for trial in syphilis.

The following experiments have been made to determine the action of this substance on animals infected with the spirochetes of yaws.

Rabbit 1.—April 1, inoculated in left testicle with material from Rabbit C (first generation from human case). May 6, nodule palpable, spirochetes present; thirty-six days. May 7, spirochetes present. May 9, nodule size of olive; serum negative; 0.1 c.c. injected intravenously with 0.0045 gm. 606 per kilo. May 10, spirochetes not found. May 12, nodule not palpable. May 21, nodule not palpable. June 3, nodule not palpable. June 16, under ether anesthesia, testicle removed; no lesion; spirochetes not found; serum negative.

Rabbit 15.—March 31, right testicle inoculated from Rabbit 7 (second generation). May 7, nodule palpable, spirochetes present; thirty-seven days. May 9, treated as above, intravenously; serum negative; nodule size of olive. May 10, spirochetes not found. May 12, lesion size of pea. May 18, lesion not palpable. May 28, rabbit dead; testicle shows no lesion.

---

[2] Nichols: Proc. New York Path. Soc., 1910, x, 1.

[3] Alt: München. med. Wchnschr., 1910, lvii, 561; Iversen: München. med. Wchnschr., 1910, lvii, 777.

Rabbit 17.—April 14, left testicle inoculated from Rabbit 6 (second generation). May 7, nodule palpable, spirochetes present; twenty-three days. May 9, treated as above, subcutaneously; serum negative: nodule size of pea. May 10, spirochetes not present. May 12, spirochetes not found. May 18, lesion not palpable. June 16, under ether anesthesia, rabbit castrated; no lesion; serum negative.

Rabbit 21.—April 22, right testicle inoculated from Rabbit 9 (third generation). May 14, nodule palpable, spirochetes present; twenty-two days. May 23, serum positive. May 24, spirochetes present; treated as above, intravenously. May 25, spirochetes not found. May 27, serum positive; lesion not palpable. May 31, serum positive. June 14, lesion not palpable; serum positive. June 17, under ether anesthesia, rabbit castrated; no lesion. June 23, serum negative.

In several animals, the serum reaction has persisted a number of days after the removal of the focus of infection.

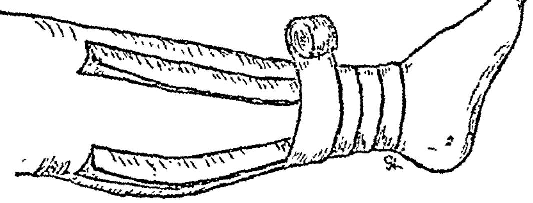
In all these animals no spirochetes could be found twenty-four hours after the treatment; the lesion disappeared after two or three days and, except in the last case, no complement fixation reaction occurred.

In animals not treated, the lesion, as noted above, persists several weeks at least and the serum reaction occurs in one or two weeks. These animals were, therefore, permanently cured by a single small dose. Rabbits tolerate a dose thirty times as great as the one given.

Three monkeys infected on the eyebrow have also been treated in a similar way and the lesions have disappeared after twenty-one days.

It would seem worth while to try this remedy in our tropical possessions where the natives are frequently, and white men are occasionally, infected.

Bandage for Cone-Shaped Surface.—Dr. Maynard C. Harding, Ault, Colo., says: The excellent bandage described by Dr. G. W. Putnam (The Journal A. M. A., April 30, 1910, p. 1441) prompts me to report a similar method of applying a bandage to any cone-shaped surface. Cut three strips of 2-inch adhesive plaster the length of the completed bandage—two will do for an arm-dressing. Fold them lengthwise with the sticky side out, and apply to the limb at equal intervals. Put on the first layer of roller as usual; then one strip of adhesive plaster applied in the same manner will suffice for each successive layer, making a bandage of exceptional strength and durability. It can be especially recommended for a knee-dressing where it is desired to limit the motion.



A firm bandage for any cone-shaped surface.

One reads much of starch bandages in works on surgery, but they are seldom found in the average office. A very satisfactory substitute can be made with the help of a bottle of thin glue or quickly drying cement. A few dabs of glue on every other layer of bandage as it is applied will convert it into a solid mass. This method can be used to apply further layers to the adhesive bandage described above, or with Dr. Putnam's bandage.

THE RELATION OF MOSQUITOES TO FILARIASIS IN THE REGION OF SAN FRANCISCO BAY*

CREIGHTON WELLMAN, M.D.
EDWARD VON ADELUNG, M.D.
AND
FINLEY M. EASTMAN
OAKLAND, CAL.

The constant presence of filariasis in the cities bordering San Francisco Bay has long rendered it desirable to know if the indigenous mosquitoes of this region are efficient hosts for the parasite at the temperature normally found in this part of California. In other words it is a desideratum to learn if an Oriental infected with filariæ residing, for instance, in Oakland might be a *menace* to the community in which he lives. With this object in mind we have undertaken some experiments.

REPORT OF EXPERIMENTS

The Source of the Filariæ.—A Japanese man, aged 29, was found on Dec. 10, 1909, to have sharp-tailed, sheathed filarial embryos in his night blood. This man came to San Francisco six years ago from Japan, stopping at Hawaii three months on the way. He went to Alaska four years ago and since his return to California has resided for three years in Oakland.

The Mosquitoes Used in the Experiments.—These were all bred from larvæ collected in rain-water barrels, etc., which on breeding out proved to be two common species already reported from this part of California, namely, *Culex consobrinus* (Rob.-Desv.) and *C. tarsalis* (Coq.). The males soon died in captivity but the females were easily kept alive in gauze cages, protected from bright light and fed on fresh grapes, which they readily sucked.

Time and Manner of Feeding.—The patient's blood was first examined late at night and proved to contain microfilariæ in plenty, and the mosquitoes were then removed from the cage in glass tubes and wide mouthed bottles, care being taken not to injure the insects. These containers were inverted over the flexor surface of the patient's forearm. It was found that some of the mosquitoes fed very slowly, in several instances an hour elapsing between the time the tube was placed on the arm and the mosquito's beginning to suck blood. When the insects had fed to repletion they were transferred to a cage containing a dish of water and kept at the ordinary temperature of the laboratory with some protection from the light. On the seventh, fourteenth and twenty-first days, after feeding, part of the mosquitoes were dropped alive into 80 per cent. alcohol, an equal number of controls which had fed only on fruit being treated in the same manner each time, and the bottles carefully labeled. To prevent error, two lots of mosquitoes were fed and controlled after this method, the dates of the first feeding of the two lots being December, 1909, and January, 1910, respectively.

Technic Employed in Preparing the Mosquitoes.—This may be described under two heads, namely, (1) fixing and hardening of mosquitoes, and (2) staining and mounting.

Under the first head it will be remembered that the insects had been dropped alive in 80 per cent. alcohol. They were removed from this and the legs and wings cut off. Next they were placed in 95 per cent. ethyl alcohol for twenty-four hours. From this they were transferred to absolute alcohol for twenty-four hours. From absolute alcohol they were put in absolute alcohol and ether (equal parts) for twenty-four hours. From this mixture they were transferred to ether for twelve hours. From the ether they were placed in 3 per cent. celloidin for three days and afterward into 6 per cent. celloidin and placed in 80 per cent. alcohol to harden for twelve hours. The specimens were then sectioned and the sections kept in 80 per cent. alcohol previous to staining.

---

* From the Laboratory of Tropical Medicine, Oakland College of Medicine.

* Published under the *imprimatur* of the American Society of Tropical Medicine.

Under the second head we may record the following steps. The sections were taken from the alcohol and placed in tap-water to remove the alcohol. Next they were stained with Delafield's hematoxylin for two minutes and afterwards washed in tap-water to remove surplus of stain. Acid alcohol (95 per cent. ethyl alcohol with 1 per cent. hydrochloric acid) was used to differentiate the sections, the sections being placed for three minutes in this mixture. Next the specimens were placed in 95 per cent. alcohol for three minutes to dehydrate. The sections next were passed through beechwood creosote for five minutes to clear them and finally fixed on slides and mounted in xylol balsam under cover glasses.

Result of Examination.—No developmental forms or other extraneous bodies were seen in the thoracic muscles or any other part of the sectioned mosquitoes. The appearance of the mosquitoes fed on the patient's blood is identical with that of the mosquitoes used for controls. As the sections are thin and the staining good, and as Dr. Wellman is familiar with the appearance of developmental forms of filariæ there seems to be little room for mistake.

Conclusions.—We consider that we have shown by this experiment that the two commonest species of Culex mosquitoes in Oakland are not efficient hosts at room temperature for the nocturnal sheathed microfilariæ occurring in our Japanese patient. It is possibly not too much to say, in view of these findings, that there is probably little danger that Orientals who are infected with filariæ will infect the inhabitants of the San Francisco Bay cities under present conditions.

Therapeutics

ULCER OF THE STOMACH AND DUODENUM

It is the object of this department not only to present sensible treatment for disease and to suggest a method of carrying out that treatment, but also to aid the clinician in making his diagnosis and hence to establish the correct treatment.

Besides gall-bladder disturbances and recurrent appendicitis which all give epigastric symptoms, and other reflexes from abdominal disease or conditions, ulcer of the stomach and duodenum must be diagnosed from the neurosis, gastralgia, and from cancer of the stomach.

ULCER OF THE STOMACH

The principal symptoms are pain and vomiting. The pain is circumscribed and boring in character, sometimes shooting through to the back, intermittent, mostly after eating, rarely on an empty stomach, and is increased by pressure, as by corsets, bands, and belts. The greatest intensity of the pain is located somewhere in the stomach region. The vomiting is likely to occur immediately or soon after eating, and is often projectile in character. The vomiting of blood is, of course, highly distinctive, but does not always occur, and the blood may be fresh and arterial or more or less coagulated and partially digested and rarely of the coffee-ground variety. The appetite is generally good, especially for meat. There is often thirst; pyrosis and flatulence, rarely; there is generally hyperchlorhydria, and meat is thoroughly digested. Attacks of diarrhea are likely to occur, and the stools often contain occult blood. There may develop anemia, more or less severe.

ULCER OF THE DUODENUM

The principal symptom is pain, more or less localized in the region of the pylorus, intermittent, occurring generally about two hours after a meal. In other words, this pain occurs when the stomach is more or less empty. This pain is more frequently relieved by eating some bland food or drinking milk than is the pain of ulcer of the stomach. The appetite is generally good, and vomiting and other symptoms of gastric indigestion are infrequent. Attacks of diarrhea may occur, and occult blood is often present in the stools. There may be a marked hyperchlorhydria.

GASTRALGIA

Gastralgia or stomach cramp may be a neurosis, or may be caused by any irritant in the stomach. While severe gastralgia may cause cardiac depression and simulate angina pectoris, it most frequently allows a prognosis of perfect safety to the patient, and occurs generally in a neurotic patient or hysterical woman. The pain is never so severe as these patients think it is, is often entirely relieved by eating, and is accomplished by enormous amounts of eructated, odorless gas. Burning is often complained of, but pyrosis rarely occurs. Digestion is generally found good when tested. Burning pain and gas eructations are irrespective of the kind of food eaten. The appetite is, of course, capricious and the pain is generally relieved by food and pressure, in fact, pressure is well borne. Nausea and vomiting are rare.

CANCER OF THE STOMACH

The above three conditions may occur at any age, but more generally before 35, while cancer of the stomach occurs more generally from 40 to 60. The principal symptom is pain, generally localized, often in a region that is felt to be a mass or tumor which is exquisitely sensitive to pressure. The pain progressively becomes worse, the mass progressively grows, and emaciation and cachexia progressively increase; hence a patient who has upper abdominal pain of a duration of much more than six months, without presenting any appearance of cachexia and without having lost much weight, can be almost guaranteed not to have cancer. Other symptoms of cancer of the stomach are loss of appetite, eructations of fetid gas, pyrosis, often repeated vomiting, sometimes days at a time and then a period of rest, with frequently, of course, signs of dilatation of the stomach. Rarely is fresh blood vomited; generally extravasations of blood remain long enough in the stomach for decomposition and when vomited give the appearance of coffee grounds. The stomach poorly digests food, often contains no free hydrochloric acid after a test meal, generally lactic acid, and, if the cancer is near the pylorus, the Boas-Oppler bacillus.

A TEST FOR BLOOD IN THE FECES

Many cases of gastric and duodenal ulcer can only be diagnosed by the symptoms of these conditions plus the finding of occult blood in the feces. A small portion of fecal matter about the size of a hazelnut is mixed with water, and to this watery mixture is added a small quantity of glacial acetic acid. This is then placed in a test tube and shaken with ether. Any hemoglobin which may be present is changed to hematin by the acetic acid and taken up by the ether. After settling, the ether which rises to the top of the solution is poured off and to it a solution of guaiac in alcohol is added. To this is added 1 c.c. (15 minims) of the resin of turpentine. The change of color denotes whether blood is present or not. If blood is present in any amount it quickly changes to blue. If there is but a small quantity of blood the change requires some minutes. Before applying this test there should be no meat allowed in the diet for forty-eight hours, to preclude the possibility of the blood test being given by the eating of a meat which contained blood.

TREATMENT

While it is wise, and will be found wise, to operate more frequently for gastric and duodenal ulcer than has been done, the seriousness of the operation is such that every effort should be made to cure the condition medically. The greatest danger from these ulcers causing serious hemorrhage is in their early history, and probably it is at this time that they are most amenable to medical treatment. It is not frequent for patients to die from hemorrhage from an ulcer in these regions, but the fact that it does occur, and the fact that perforation may occur, and the fact that constant hemorrhages may cause profound anemia, makes the condition serious from the very beginning. Again, these ulcers so frequently become quiescent or apparently heal only to cause symptoms later, that it is hardly safe to decide that an ulcer in the region is cured until after the lapse of at least a year, and perhaps two years, of freedom from symptoms.

In attempting to cure an ulcer of the stomach or duodenum the diet becomes of primary importance, as it is the food that is continuously to aggravate the condition. As hyperacidity seems to increase the ulceration, certainly increases the pain, and is likely to increase the vomiting, anything that diminishes the acidity is good treatment, and a diet free from the substances that cause the greatest outpouring of hydrochloric acid is the diet of choice. In other words, a diet without meat and without meat broths, without toast, and without any hard particles of food that can scrape or irritate the inflamed part, should be selected. On the other hand, it does not always seem that a large, straight milk diet, with the probable production of lactic acid and gas during its digestion, is advisable or beneficial. Neither does it seem sensible to prescribe a starvation diet or a total abstinence from food, with rectal feeding which is always insufficient, to cure an ulceration that at the best must require weeks to heal, and this in a patient who is already debilitated and probably anemic. Therefore, the so-called Lenhartz diet with raw eggs is the most sensible as giving nutrition and at the same time inhibiting the production of hydrochloric acid and tending to heal the ulcer.

The raw eggs are beaten up whole and placed in a cup or glass surrounded by ice. The small amount of milk given is also served iced in the same manner, and the egg and milk feedings alternate with each other every two hours, at first two teaspoonfuls of the egg and four teaspoonfuls of the milk. The first day two eggs are used and six ounces of milk. The eggs and milk are gradually increased from this minimum until by the sixth day seven eggs and twenty-two ounces of milk are given. From the third day on a little granulated sugar is added. At the end of a week the number of eggs is reduced and some scraped beef is allowed, with soon a small amount of boiled rice. During the following week, the second week, the eggs may be soft boiled, and four may be administered a day, with the milk increased to nearly a quart, sugar as before, and scraped beef or chopped chicken and rice or bread with a little butter may be gradually added and the diet thus varied. Even when the eggs are used soft boiled, four should be taken a day. Whatever is taken, if solid, it should be very completely and slowly masticated, and as above stated, at first the amounts ingested at one time must be very small and taken at intervals of two hours during the day. The foods for the first week should be taken cold and the next week only warm, never hot. Small sips of iced water may be taken as often as desired or advisable.

During the first week the patient should be fed, not even allowed to feed himself, and he should remain in bed for at least three and better four weeks.

If there is hemorrhage, an ice-bag should be placed over the stomach and a large dose of bismuth subnitrate should be administered, perhaps 3 or 4 grams (45 or 60 grains) at once.

It generally seems advisable to give bismuth in large doses, at least 2 grams (30 grains) once a day. This can be taken stirred up in water or in milk and quickly drunk.

The treatment above suggested generally stops the pain. If pain is still severe morphin should be resorted to, but with this treatment it rarely will be necessary, and the dose required, hypodermatically, is small.

The patient should not get up to urinate or for the bowels; a bedpan should be used. If the patient is constipated, the bowels may be moved by the rectal injection of a half ounce to an ounce of glycerin with an equal amount of water, and soap suds could be used if needed.

As these patients are already short on iron and for a number of days are to receive no meat, it is advisable to give the saccharated oxid of iron (*Eisenzucker*), 3 grains, in tablet form, twice a day. The patient should thoroughly crush the tablet with the teeth before swallowing.

If after a month of this treatment the patient cannot normally convalesce and be apparently cured, in other words, if the symptoms quickly return, an operation should probably be recommended, as the future of such a recurrent case is uncertain. Recurrent severe hemorrhage should cause operation, and, of course, when there is perforation operation is immediately necessary.

FACIAL SPASM AND TIC; TORTICOLLIS

The general practitioner may as well in the first place admit that there is a scientific, psychopathic method of treating patients suffering from nervous mistakes, and in the second place, that such treatment can be carried out successfully only by physicians who have made this branch of therapy a special study.

These points being agreed on, it is most satisfactory to note that Dr. Tom A. Williams, of Washington, D.C., declares (*Monthly Cyclopedia* and [illegible], January, 1910) that many of the supposed incurable and most distressing spasms of the face and neck muscles may be cured. In this paper he ably and carefully discusses the diagnosis of the above conditions from chorea and from the more serious cerebral disturbances. He cites a number of illuminating cases, but does not go into the technic of treatment. If he did, it would hardly be of value to the general practitioner, as if the above preamble is correct and agreed to, patients suffering from these muscle contractions, terrible to themselves, distressing to their friends, and causing moral suffering almost beyond measure, should be referred to a physician who has made a special study of psychopathic treatment.

The object of this reference is to call the attention of physicians to the fact that in many of these supposedly hopeless cases a cure may be effected.

SATURDAY, JULY 16, 1910

MEDICAL MEN WIN RANK IN THE ARMY

Major-General Leonard Wood has returned from South America and this week assumes his duties as the senior general officer of the United States Army. Next in rank is Adjutant-General Fred C. Ainsworth. Both are medical men who entered the army as surgeons. That they should have been able to break through the conservatism of military administration, and to advance so far into fields usually closed to their profession, is to the credit not only of their abilities and force of character, but of the Army itself, which has demonstrated its ability to rise above ancient prejudices and traditions and to utilize its best material. That the Medical Corps should contribute at the same time the senior line officer and the senior officer of the staff is an event sufficiently remarkable to call for more than passing notice.

General Leonard Wood was born at Winchester, N. H., Oct. 9, 1860, and graduated from Harvard Medical School in 1884. In January, 1886, he entered the Medical Corps, and soon distinguished himself in an arduous campaign against the Apaches. The Spanish War found him on duty in Washington where he had made acquaintance with a congenial spirit in the then Assistant Secretary of the Navy, Theodore Roosevelt. A like vigor of mind, combined with moral force and a love of rude physical exercises, drew these men together, and so when war was declared and the command of the regiment of "Rough Riders" was offered to Mr. Roosevelt, he told the President that Dr. Wood was by reason of his twelve years' experience in the Army much better fitted to cope with the technical difficulties of enlisting, equipping and training a new regiment than he, and he proposed that Wood should be appointed colonel and he lieutenant-colonel. This was done, and the fight at Las Guasimas made Wood a brigadier and gave the regiment to Roosevelt.

After the capture of Santiago, Wood was placed in command of that district and in the space of a year his capacity for organization had so clearly demonstrated itself that he was transferred to Havana and made the military governor of Cuba with the rank of major-general of volunteers. In three years he brought Cuba from a naked and devastated land where famine and disease stalked hand in hand, to salubrity and plenty. The death rate in Havana fell from 91 per 1000 in 1898 to 20 in 1902. In the thirty years preceding his appointment as governor there were in the city of Havana 21,448 deaths from yellow fever and 12,722 from smallpox. In the decade since that date there have been 44 deaths from yellow fever and 4 from smallpox.

But the sanitary regeneration of Cuba and the support and assistance given to the Reed yellow fever board are only a small part of the creditable work of the military governor of Cuba. In every direction in which constructive statesmanship can influence the destinies of a nation, the work of Leonard Wood has left an indelible impress on the government and lives of the Cuban people.

In the twelve years since his taking up the duties of a combatant officer, General Wood has held many important commands at home and in the far east and has been an assiduous student of the military profession. His mastery of it is demonstrated by the practically unanimous approval with which the Army received his assignment as Chief of Staff.

The career of Major-General Fred C. Ainsworth, the Adjutant-General of the Army, while less spectacular in character and far less familiar to the public than that of General Wood, is an equally creditable example of the uplifting power of high ability joined to force of character.

He was born at Woodstock, Vt., Sept. 11, 1852, graduated in medicine at the University of the City of New York in 1874 and entered the Army as assistant surgeon the same year. For twelve years he performed the routine duties of a medical officer, most of this period being passed amid the breezy and often exciting surroundings of the western and southwestern frontier. When in December, 1886, he was placed in charge of the record and pension division of the surgeon-general's office, a condition of affairs confronted him which was of grave concern, not only to the War Department but also to the President and to Congress, and which threatened to become a question of national politics. These were years of great activity in granting pensions, and for each application, the medical record had to be sought in the hospital registers, of which there were more than 20,000 volumes, and the record of service verified by consulting the muster rolls, of which there were about 400,000, in every stage of dilapidation. The former was done in the surgeon-general's office, the latter in the adjutant-general's, and each was several months in arrears. The pension office charged all delays to the War Department and the cry went up that a Democratic administration was obstructing the carrying out of the pension laws. By the introduction of good business methods and business discipline among the three hundred clerks of his division, Captain Ainsworth in three months caught up and was enabled to answer each call from the pension office within three days. He then set part of his force to copying the hospital records on cards so that all the entries for each soldier were brought together and could be instantly obtained. When this was completed all applications were answered within 24 hours. A special committee of the Senate which investigated the methods of business in the executive departments recommended the extension of Ainsworth's methods to the other bureaus of the War Department, and the Secretary of War, Mr. Proctor, in 1889, consolidated fourteen divisions of the War Department with 700 clerks into the record and pension division, which was placed under Captain Ainsworth, assistant surgeon. The adjutant-general's office unloaded on him in June, 1889, 40,000 unfinished cases and by the end of September all were disposed of and the current work was well in hand. Congress in 1892 erected this division into a permanent bureau, of which Ainsworth was made the head with the rank of colonel. An additional division of the adjutant-general's office was added to it in 1894 and in 1899 Congress still further enlarged it by the addition of the war records office and raised the rank of its chief to brigadier-general. In 1903 Secretary of War Root still further enlarged it and finally in 1904, on his recommendation, Congress consolidated the record and pension office with what remained of the adjutant-general's office after the transfer to the general staff of the advisory functions formerly exercised by the adjutant-general. The head of this new and great office, which distributes and keeps record of the vast business of the War Department and is its mouthpiece, and which is charged with the recruitment of the Army, besides being the custodian of all of the records of all of our wars, was appropriately given the rank of major-general with the title of military secretary, which was later changed to the present one of adjutant-general.

It may well be imagined by those familiar with the jealousies and contentions of departmental life, that a career so full of strenuous activity and accomplishments, of which the victorious efficiency so constantly extended its boundaries, was not entirely peaceful. In fact under this brief narrative lies many a bitter struggle against narrow prejudice, crossed ambition, jealousy and sloth, besides the vast inertia of bureaucratic conservatism. The veteran Senator Cockrell, who was chairman of the special senate committee mentioned above, and than whom none knew better the inner secrets of departmental history, said on the floor of the Senate in advocating General Ainsworth's promotion: "General Ainsworth has done a work which has never been equaled by any executive officer of this government from 1789 to date, and I challenge any comparison with his record."

Members of the medical profession may be permitted to take some pride in these achievements of their confrères.

METHODS FOR THE QUANTITATIVE ESTIMATION OF ALBUMIN IN THE URINE

Clinicians have long been dissatisfied with the results yielded by the Esbach method for the quantitative estimation of albumin in the urine. The dependence of this method (1) on an exact room temperature, (2) on dilution of the urine when the albumin is large in amount, and (3) on a constant acidity are well-known difficulties. Moreover, the precipitate formed often settles unevenly; there is sometimes difficulty in making a correct reading of the meniscus in the tube and, finally, the picric acid in the solution makes it objectionable to handle on account of the staining of the hands and clothes in case of accident. A distinct advance in the quantitative methods of estimating the albumin in the urine was made by Tsuchiya when he introduced his solution consisting of phosphotungstic acid, hydrochloric acid and ethyl alcohol.

The recent study of Mattice[1] shows the great value of Tsuchiya's reagent[2] when used in a certain definite way. Mattice made a large number of control observations with other methods, with results which speak strongly in favor of the use of Tsuchiya's reagent. He finds that the phosphotungstic method is much more accurate than the Esbach method for comparative quantitative estimation of albumin in the urine and urges that Esbach's solution be supplanted altogether in clinical work by Tsuchiya's reagent. The readings are very little influenced by changes in temperature; foaming or floating of the precipitate is rarely seen; the precipitate settles much more evenly than with the Esbach reagent; it is easy to read the meniscus accurately at the mark on the Esbach tube and no dilution of the urine is necessary.

The method is applicable to high grades of albuminuria as well as to the slightest grades. It can also be used where the albuminuria is complicated by glycosuria. The solution is easily prepared, keeps well and does not stain the hands or clothes. It can, therefore, be warmly recommended for clinical use.

THE BRIEF IN DEFENSE OF THE TEN-HOUR LAW FOR WOMEN

The Illinois Supreme Court recently declared constitutional a law limiting the working-day of women in factories and laundries to ten hours. This decision, aside from its intrinsic interest, is noteworthy because in the arguments for the bill and in the decision rendered by the court stress was laid, not on the legal aspect of the question, but on the demands of public health. The brief submitted to the Supreme Court in defense of the ten-hour law contains but twenty-four pages of legal matter, the remaining five hundred odd pages being devoted to a review of the literature on fatigue.[1] The document thus becomes one of great interest to physicians, for it is probably the most nearly complete compilation that has ever been made of the publications, both medical and sociological, on the subject of what we must, for want of a better word, call "overwork."

---

[1] Mattice, Albert F.: The Quantitative Estimation of Albumin in the Urine, Arch. Int. Med., March 15, 1910, p. 313.

[2] Tsuchiya's method was mentioned in THE JOURNAL, July 25, 1908, p. 333. The reagent is a mixture of 1.5 gm. phosphotungstic acid: 5 c.c. concentrated hydrochloric acid, and ethyl alcohol enough to make 100 c.c. This is used in the Esbach tubes in place of the old picric-citric-acid solution, with technic similar otherwise.

Although the primary object of this brief is to show that the demands of public health require legal restrictions on the work of women because of the peculiar importance to the community of the health of mothers, yet the brief is not limited to the consideration of the overwork of one sex only, but discusses fatigue in all its aspects. The experimental work of Mosso, Helmholtz, Ranke, DuBois-Reymond, Weichhardt and Wolff-Eisner is reviewed. The investigations of German, Italian and French writers on the effect of overwork on the different organs, on the effect of night work, of prolonged standing on the feet, of foot-power machinery, of the speeding up required by the "piece-work system," are fully given. There are also to be found statistics of great interest drawn from the working-class insurance records of Germany.

To the American reader one striking feature of this review of the literature is the small part which our country has taken in this most modern field of research. Quotations from American sources are hard to find and when found they consist chiefly of reports of factory inspectors. Few well-known American names are found in this brief. On the other hand, the foreign quotations bristle with familiar names and it is evident that industrial hygiene ranks as high as any other branch of medicine in Europe. Men who are authorities in physiology, pathology and medicine have investigated the effects of fatigue in the different industries, and practicing physicians of the first rank have appeared before legislators to testify in favor of legal restrictions. When the question of early closing was agitated in England in 1888 a bill to shorten the working-day was introduced by the noted scientist Sir John Lubbock and was supported by a petition from the medical profession signed by such men as James Paget, Richard Quain and W. S. Playfair.

There are some very interesting statistics in this brief as to the increase of nervous diseases which accompanies the increased speed of industry and the greater strain on the attention. Thus the State Invalidity Department of Berlin reported in 1906 that 35 per cent. of the cases treated were neuroses of the heart. Nervous breakdown accounted for over one-half of the men patients during the year and over one-third of the women.

The effect of fatigue on the occurrence of accidents is graphically shown by French and Belgian statistics. The number of accidents increases progressively during the morning hours, drops after the noon intermission and then rises from hour to hour till the end of the working-day, affording a practical illustration of Helmholtz' experiments in attention fatigue.

While the health of the woman herself is important to the community, the effect of her good or ill health on the coming generation is even more important, and as this is one of the strongest points in Mr. Brandeis' argument, we find many statements as to the effect of overwork in women on their fecundity and on infant mortality. The most extensive study of the effect on fecundity seems to have been made by Broggi, who states that of 172,365 Italian women between the ages of fifteen and fifty-four years who were employed in industrial occupations, the average child-bearing coefficient was only 45 per cent. or about one-third of the general fertility of Italian women (120 per cent).

Infant mortality in Germany and England seems to increase progressively according to the increase in the proportion of women engaged in industrial work, and this is true even if the mother's work results in a higher standard of comfort in the home. The two classical demonstrations of this rule are the great Lancashire cotton famine and the siege of Paris, during both of which crises there was loss of employment and great privation. In spite of the starvation and the increased general death-rate the infant death-rate fell, in Paris actually 40 per cent., simply because the women, being out of work, were obliged themselves to nurse and to care for their children.

The overwork of women is not so crying an evil in this country as in Europe, for the number of married women obliged to work outside of their homes is far smaller here, but it must be remembered that in many states the child-labor laws are far from adequate, and even in those states where children under fourteen are forbidden to work, there is still ample time between the age of fourteen and the girl's marriage to allow of serious and permanent injury to health—injury which may result in childlessness or in the bearing of sickly children. It is a matter of common observation that the first generation of children born in this country of foreign parents are inferior in physique to their peasant parents; yet it is precisely these girls who go into the heaviest kinds of factory work and have the longest working-day. It is also these girls who are the coming mothers of the American nation.

Since it is impossible to control beyond a certain point those trades which make especially severe demands on the endurance of women workers, the obvious course seems to be to restrict the number of hours which women may be employed in them. The ten-hour law is a step in the right direction, but it is probable that this generation will not pass away without seeing still further steps taken.

---

[1] Brandeis, Louis D., assisted by Goldmark, Josephine: Brief and Argument for Appellants. In the Supreme Court of the State of Illinois December term, 1909. This is essentially the same brief as that with which Mr. Brandeis successfully defended the ten-hour law for women in Oregon. It is, however, much more exhaustive than the first one.

THE FUTURE OF THE MEDICAL PROFESSION

Dr. Victor C. Vaughan[1] has made an interesting analysis of the present condition of the medical man in this country, in relation to society in general, to industry and to the other professions. He also ventures to make some prophecies regarding the trend of medical science and the place and office of the future practitioner. Dr. Vaughan shows what has been accomplished in this country for the elevation of the profession through an awakened professional conscience, a high code of ethics and harmonious organization. "This is a commercial age and this is preeminently a commercial country, and yet the medical profession is ridding itself of commercialism. It is demanding of those who desire to enter its ranks a higher degree of culture and intelligence than is demanded of any other profession in this country." He sees the activity and usefulness of the physician rapidly expanding and becoming devoted more to the uplift of mankind than to financial gain. "The world has never been in greater need of the enlightened medical man than it is likely to be in the next generation, and the world will demand that he be worthy of the tasks that will fall on him. No other profession will be able to render greater service to mankind."

In view of the great and increasing cost of medical education and investigation in medical sciences, Vaughan thinks that the government should help to pay for them. "The nation that will profit in the future from the labors and discoveries of the profession must help in this cause. It must make large appropriation for scientific research. It must render financial aid to medical education, which has become too costly for the profession itself to provide, and it must not permit the use of short roads to practice. While the advanced medical educator in this country is doing his best to elevate his profession, pseudo-medicine is filling the lobbies of every state capitol with demands for legal recognition, and too often it happens that our law-makers do not distinguish between the true and the false. This imposes a heavy duty on the profession, namely, the education of the public."

Dr. Vaughan enumerates some of the specific ways in which the medical profession can be of service to humanity, and some of the measures necessary to free the race from disease. Among these are the education of the public in the nature of infectious diseases, and the inauguration thereby of measures to restrict and eradicate such pests; the placing of venereal diseases on the list of dangerous and communicable disorders, and the holding in custody of all persons so affected; and the routine medical examination of every person at least twice a year. This last suggestion gives a wider scope to a plan broached by Professor Irving Fisher, already noticed in The Journal. Unless all signs fail (for many other thinkers have read them in the same sense), the trend of our professional future would seem to be in the direction indicated by Dr. Vaughan, or something closely parallel thereto.

One deduction from these premises, however—it seems to us to be an inevitable one—Dr. Vaughan refrains from drawing, namely, that unless science discovers some way of extracting professional fees from stones, or nutriment from air, there must be a readjustment of the financial relations between the medical profession and the public. Already the profession feels the hardship of having to maintain non-commercial standards while making a livelihood by offering specific individual services to a commercially minded public; and already that commercially minded public begins to realize that every effort of the medical profession to widen the sphere of its public service narrows the circle within which its members may reap individual rewards. What is to be the result in the day when the highest medical skill shall be directed toward the prevention of disease, and an epidemic shall as clearly point to reprehensible neglect on the part of some responsible person as a train-wreck does now? Shall we ever be able to persuade our patients to fee us, as the Chinese are said to pay their physicians, so long as they remain in health? Even if the occidental mind could be brought to regard this procedure as natural, there is an obvious difficulty in the fact that many of the most important works of preventive medicine are not performed for the benefit of any individual; they are public services, and must be paid for, if at all, by the public. Until the day comes, therefore, when the physician's work shall be recognized as essentially a public function, the conscientious physician must be content to regard himself as an unpaid public servant, whose right hand and left are perforce ignorant of each other's doings, since the one is hastily snatching at the indispensable bread and butter, while the other is helping to usher in the new and—let us hope—better order of things.

Current Comment

MALTA FEVER

Commenting on a question recently asked in the British House of Commons, relative to the infection of goats with Malta fever, *Nature*, June 16, says that what makes these animals so dangerous in the spread of the disease is the fact that they themselves are so immune. If Malta fever caused in the goat high fever and the other symptoms that it does in man, the animal would cease to be a danger. It would be confined to its stable and its milk would run dry. As it is, the infected goat keeps in apparent perfect health; and therefore the Maltese themselves refuse to believe that the disease is spread through the medium of the milk and have been exporting their infected goats and thus spreading the disorder. Last year the Sleeping-Sickness Bureau of the Royal Society discovered it infecting a large proportion of the native population on the shores of Lake Albert Edward in Uganda, and the native goats were found to be the carriers. Some Maltese goats imported into the United States in 1906 were found to be infected, and but for the rigid quarantine we might have had the disease epidemic here. As it was all the animals, and even the kids born here, had to be slaughtered within two years to prevent the spread of the infection. The prohibition of the use of goats' milk has completely abolished the disease in the British soldiers and sailors in Malta, though it continues to prevail among the native population. It seems strange that the exportation of Maltese goats should be permitted by the British government or that their importation should be allowed by any other—it is, as *Nature* says, almost beyond belief that it should be so. The importation or exportation of the carriers of an acute infectious disease like Malta fever is hardly comparable with that of tuberculous cattle, as *Nature* seems to infer, though that is sufficiently undesirable to call for restrictions.

---

[1] Address on University Day at the University of Cincinnati, published in Science, 1910, New Series, xxxi, 127.

SANITARY REFORM IN TURKEY

Since the revolution in Turkey with the Young Turkish Party in control there seems to be a better prospect for health and hygiene in the Turkish capital. In former times, any proper medical treatment of Turkish women was rendered impracticable by Mohammedan custom. The advent of women missionary physicians, who were allowed to see their patients, probably started the breaking down of the barriers and gradually there has come a change so that at the present time many Turkish women readily submit to the necessary examinations and treatment by the physician. The change has been accelerated by recent events. One of the most striking changes reported is that of public lectures on hygienic subjects, which seem to be fairly started under the auspices of the American College for Girls in Constantinople. This would have been impossible under the old régime, but in the existing conditions the movement seems to have a very promising future. It will take a long time, of course, to reform the many sanitary deficiencies of the Turkish capital and still longer in the provincial towns and rural districts, but a start appears to have been made and prominent Turkish physicians are actively cooperating in the work.

A CENTENNIAL OF THE WATER-CLOSET

In 1810 the water-closet came into general use in Germany and the Germans are this year celebrating "the centennial of the water-closet." Thirty-five years before that date—that is, in 1775—the first British patent ever granted for a water-closet was issued to Alexander Cummings, a watchmaker; while twenty-three years after —or in 1833—the first American patent was taken out. Like all innovations, it came into general use but slowly, and it was not until 1852 that its value was officially recognized. In that year a municipal ordinance for the city of London went into effect that brought the modern system of sewers into being, and with it the general introduction of water-closets. Who at first could have realized the importance of these few quarts of water in a reservoir as solving the problem of permitting sanitary existence in large cities? To-day the water-closet may be regarded as the stamp of civilization; not until a water-closet system is installed can any populous community now rank as civilized and up-to-date.

HONOR TO CROOKES

The British government has conferred the Order of Merit on Prof. William Crookes in recognition of his eminent work in chemistry and physics. This order, established by King Edward VII as a special distinction for men eminent in science, literature or art, is limited to twenty-four members within the British empire, Lord Lister and Sir Joseph Dalton Hooker being the only members of the medical profession so honored. This well-deserved distinction comes to Professor Crookes as a recognition of his standing as one of the foremost chemists of to-day. His most prominent achievements have been the discovery of thallium in 1861, the invention of the Crookes tube, by means of which Roentgen discovered the *x*-rays, and his investigations bearing on a large number of important problems associated with commercial and theoretic chemistry. In 1898 the British Association for the Advancement of Science elected him president, while many scientific bodies have honored him with office or membership. The appointments of Sir William Crookes and Mr. Thomas Hardy, the well-known English novelist, on whom the honor was conferred at the same time, leaves but a single vacancy in the order.

COMPLETE REPORT ON MEDICAL CURRICULUM

Two years ago the Council on Medical Education, recognizing the tendency to overcrowd the medical curriculum, appointed a special committee to make a careful study of the comparative value of each of the subjects taught and to bring in a report recommending what might be termed a model or standard curriculum. Special pains were taken to have this curriculum represent the ideas, if not the ideals, of as large a number as possible of leading medical educators who would represent all sections of the country. The Council selected chairmen for ten subcommittees and each of these chairmen was asked to recommend fifteen other educators in his subdivision of medicine and, from the names submitted, nine additional selections were made for each subcommittee, making a total of one hundred for the entire committee. These committees entered on the work with remarkable energy and enthusiasm, numerous meetings were held, an enormous amount of correspondence was carried on, ideas were submitted to and suggestions obtained from a large number of other educators acting in an auxiliary capacity, and the result was the report on a model medical curriculum which was submitted at the last year's Conference of the Council on Medical Education. The eagerness with which copies of this report have been sought by medical and other teachers shows the deep interest which is being taken in the efforts to improve the medical curriculum. So extensive has been this demand that it was decided to issue another edition[1] of the report which would include also the discussions of the subcommittees so far as they could be obtained. The Council has clearly stated that this curriculum is advanced merely for its educational value and not with the idea that all colleges should conform strictly to it. In fact, absolute uniformity of curricula in all colleges is not desirable, although comparative uniformity would be of much benefit in permitting to students more freedom of migration from one college to another and in facilitating a larger interstate reciprocity in the licensing of physicians.

LIFE PROTECTION IN SUBMARINES

As new conditions arise in the varied human activities they necessitate new provisions for safeguarding life. The submarine proves to be almost as dangerous for the operators as for the foe, and many lives have been lost through collision or failure of the submerged vessel to rise. Complicated arrangements have been devised for the release of the imprisoned crew or the provision of air until they can be released; but now comes a more simple invention. According to the *Scientific American*,[2] it consists of two cylindrical shells, one revolving inside the other. The outer opens both to the sea and to the interior of the vessel, while the inner and revolving one has but one opening, which may be turned to the inside of the vessel so that a man may enter, and then to the outside so as to allow escape into the water. The operation is repeated until all have escaped. Only a small quantity of water is admitted each time. It is certainly simple and if it works it may save many lives. We next need a safe means of slow descent when an airship is wrecked too far above ground to allow one to jump with safety.

Medical News

CALIFORNIA

New Hospitals.—A six-story reenforced concrete hospital, with ninety-five foot frontage, is being built on Pine Street, between Jones and Taylor, by William F. McNutt, San Francisco, and will be ready for occupancy in October. It will be furnished with suitable operating rooms, roof garden and solarium, and will accommodate ninety patients.——The Roosevelt Polyclinic has been opened at 679 Broadway, San Francisco. The following are the heads of the departments: Surgery, Drs. Walter G. Harder and Charles A. Pauson, medicine, Drs. Ralph B. Scheier and Herbert I. Bloch; gynecology and obstetrics, Drs. George K. Herzog and Walter S. Johnson; genito-urinary diseases, Drs. Louis Gross and William Edwards; skin diseases, Dr. J. Cameron Pickett; diseases of the eye, ear and nose, Drs. Albert Cohen and Oscar Tobriner; pathology, Dr. Grace Sinforth.——The Southern Pacific Railroad Company is building a new $10,000 hospital at Dunsmuir, to be completed July 1.——Work is soon to be begun on a $20,000 hospital at Lemoore.——The American Mutual Hospital Association at Taft is about to erect a new building to take the place of the present hospital.——A hospital is being fitted up at Ferndale in the building formerly occupied by the Sisters of Mercy.——The new Kaspare Cohn Hospital was dedicated June 19 at Los Angeles, the hospital being the gift of Kaspare Cohn, a wealthy resident.——A new hospital has been opened at Coalinga, called the San Joaquin.

GEORGIA

College Closes on Account of Typhoid.—Wesleyan Female College, Macon, was closed for the balance of the term on account of an epidemic of typhoid fever.

College Commencement.—At the annual commencement exercises of the Medical Department of the University of Georgia, Augusta, degrees were conferred on ten physicians. Dr. Joseph E. Allen, who has been dean of the medical college for four and a half years, retired and was succeeded by Dr. William H. Doughty.

Personal.—Dr. T. E. Rogers has been elected a member of the house-staff of the hospital at Macon.——Dr. and Mrs. Eugene B. Elder, Macon, are spending their vacation in Berlin.——Dr. Theodore E. Oertel, Augusta, has been elected president of the Antituberculosis and Sanitary Society of the State of Georgia.——Dr. John F. Harris has been appointed on the board of health at Dalton.——Dr. Robert G. Stephens has been elected city school medical examiner at Atlanta, vice Dr. Stewart R. Roberts, resigned.

ILLINOIS

New Hospital.—Work on the new hospital at Monmouth to take the place of the old building has been begun. The hospital will be ready for occupancy by April, 1911, and will cost $37,000.

Personal.—Dr. Anne J. Murphy, formerly house physician at the New England Hospital for Women and Children, Boston, has been appointed on the resident staff of the Edward Sanatorium at Naperville, to have charge of the new laboratory.——Dr. Harry C. Hill and family, Streator, have returned from abroad; Dr. Hill spent most of the time in the hospitals of Vienna.——Dr. Julius Wen Glesky, assistant superintendent and chief of the medical staff of the Eastern Illinois Hospital for the Insane, Kankakee, has resigned. He will go to the Sacred Heart Sanitarium, Milwaukee.——Dr. Charles O. Molz has been appointed assistant surgeon at Murphysboro for the Mobile and Ohio railroad.

Chicago

Less Typhoid in Chicago.—The report for the first six months of 1910 for the city shows 94 deaths from typhoid fever, equivalent to a rate of 8.3 per 100,000 of population. The rate last year, under similar computation, was 12.5 for the first half of the year. This shows the lowest record ever recorded in an American city of 200,000 population or over. The deaths from typhoid in June numbered 10.

Society of Mental Hygiene.—The Society for Mental Hygiene has been granted a charter. Among the organizers are Drs. Henry B. Favill, Sidney Kuh and Alice Hamilton, Miss Jane Addams, Samuel Alschuler and Miss Julia Lathrop. The object is the investigation of the conditions surrounding the commitment of the insane and attending to their welfare after they have been dismissed from institutions.

Report of the Milk Commission.—The preliminary report of the milk commission recently appointed by the mayor to the city council states that in the opinion of the commission, after investigation, the milk supply of Chicago as shown by high bacterial count is probably the dirtiest of any large city in the United States. The commission does not blame the health department for this condition, but states that the department is undermanned and underpaid, and that the whole matter requires further study preparatory to drafting an entirely new set of ordinances concerning the milk supply. For the present the commission recommends that means be provided for the rigid enforcement of existing ordinances by materially increasing the number of inspectors, and also that action be taken by the council to forbid the marketing of any milk at a temperature above 50 degrees F.

MARYLAND

Physician Injured.—Dr. George L. Broadrup, Cumberland, sustained severe injuries, July 8, from being run down by his own automobile. He had failed to throw it out of gear and when he cranked it it rushed forward, throwing him over an embankment and pinioning him against a house, causing a broken ankle, several fractured ribs and bad cuts.

---

[1] A copy of the complete report will be sent to any address on receipt of 5 cents for postage.

[2] Scientific American, June 18, 1910, p. 504.

Baltimore

Registration of Midwives.—The Committee of Health calls on all midwives to register by August 1. The law lately passed requires them to register at the health office and to obtain a certificate from the State Board of Health.

Health Notes.—The health report for June shows 193 cases of tuberculosis reported, as against 80 for June, 1909. This is supposed to be due to the fuller reports of the disease now than formerly. There were 89 deaths from the same disease against 83 last year. The total deaths from all causes were 798 against 722 last year; 237 were of children under 5.

Personal.—Drs. C. A. Clapp, E. A. Knorr, Carl Voegtlin, J. M. West, J. Mabry Matthews and Christian Deetjen have sailed for Europe.——At the first meeting of the Municipal Tuberculosis Commission, July 7, Dr. John S. Fulton was elected chairman.——Dr. Marshall West has been made health officer for the First district to take the place of Dr. Arthur H. Mann, who resigned on account of ill health.

Municipal Tuberculosis Commission.—The mayor has appointed the following Municipal Tuberculosis Commission: The mayor (ex-officio), Dr. Thomas McCrae, Dr. John S. Fulton, Dr. Harry Friedenwald, Mr. Henry S. Delaney, Mr. Robert Biggs and Mr. J. B. Noel Wyatt. The board of estimates has appropriated $2,500 to start the work, which aims at nothing less than stamping out the disease here.

Driving the Physician Out of Practice.—The many agencies and activities tending to drive the physician out of practice were enumerated in an address by Dr. Richard C. Cabot of Boston at Johns Hopkins recently. It was maintained that the physician is being superseded by health boards, hospitals, insurance companies and other general welfare agencies, and that the tendency is toward the support of hospitals and hospital physicians by public funds, public health being considered of supreme importance to the nation, superior even to public education. In Boston they have gone beyond most other cities in having nurses in department stores and factories. Cabot calls attention to the fact that five years ago there were twenty-five thousand medical students in the country, whereas there are now but twenty thousand, and the diminution is continuing in this steady ratio. He says physicians face this condition, but should get behind it and help it along, as there is no doubt that in the majority of instances the patient with all the facilities of the hospital, the possibility of team work among the physicians, and the trend to higher specialization, get better results from a hospital than is possible in the office of the practicing physician, and better results, i. e., better public health, is what the nation wants. It is of vital importance, and not even second to education, which the state already has assumed charge of.

NEW JERSEY

New Tuberculosis Pavilion.—A new tuberculosis pavilion located on the grounds of the Isolation Hospital at Paterson was opened for patients July 1. It is a model institution.

Sum Raised for New Hospital Building.—For the purpose of erecting a new homeopathic hospital building, the trustees, board of managers, the medical and surgical staff and the citizens' committee have succeeded in raising $100,190 in Camden, after a campaign of twenty days.

Hospital Plans Extension.—Announcement has been made that a contract has been awarded at Camden for a new building for the use of the Cooper Hospital out-patient department and for other purposes at a cost of $60,000. The removal of all private patients to this new building will enable the hospital to use the rooms now occupied by such cases in the main building, for ward purposes.

Trenton Water Supply.—Suit has been brought against the city of Trenton under the law of 1909 to compel the purification of Trenton's public water supply. Affidavits submitted show that the supply is polluted. Under the above law the state board of health has a right to institute suit in the Court of Chancery against the offending municipality to obtain purification of the public water supply. The report of the state board of health for June shows that the public is beginning to realize the value of the examination of water supplies by the state board of health, as more numerous requests for such examination are being made. The report also shows that the number of deaths from cancer has increased, the report for June showing the highest number of deaths, with one exception, for any month during the past four years.

NEW YORK

Keuka Lake Society to Meet.—The eleventh annual meeting of the Keuka Lake Medical and Surgical Association, whose membership embraces twelve counties in central and eastern New York, will be held at Grove Springs, Lake Keuka, July 21 and 22. A program of fourteen papers has been prepared. Dr. Robert M. Elliott, Willard, is president and Dr. H. B. Nichols, Syracuse, secretary.

The Fight Against Tuberculosis.—The Charity Organization Society, the State Charities Aid Association and the New York State Department of Health, organizations which are conducting the crusade in this state against tuberculosis, report that New York leads the country with 5,476 beds for consumptive patients. Massachusetts provides 2,403, Pennsylvania, 2,347, Colorado, 1,489 and New Mexico, 1,104. Facilities in this direction are, however, very inadequate.

Personal.—Dr. Mercer C. Robinson, Rochester, is in the hospital suffering from severe injuries received in a collision between his automobile and a street car.——Dr. Ira C. Whitehead, health officer of Montgomery, has smallpox, which it is supposed he contracted during a recent visit to the Immigration Bureau in New York.——Dr. Archibald M. Campbell, Mount Vernon, has sailed for Europe.——Dr. Aspinwall Judd and Dr. William J. Robinson and family, New York City, have sailed for Europe.

Harbor Pollution.—The Metropolitan Sewage Commission has reported that the sewage which is being emptied into the harbor is creating conditions which are unsanitary and a menace to public health. Tidal studies carried on in connection with the United States Coast and Geodetic Survey show that the drainage which is discharged into the harbor is not flushed out to sea but is assimilated by the water. The commission recommends that an interstate board be created by New York and New Jersey to plan a system that will protect the harbor for all time to come.

New York City

Suspicious Hospital Fires.—There have been two fires recently in the Kings County Hospital, Brooklyn. The last one on July 5 caused $2,000 damage and threatened the lives of 250 people. Investigation seems to indicate that they are due to incendiarism and arrests are expected.

The Peoples' Hospital.—This institution, situated on lower Second avenue, was dedicated June 21. It was built and presented to the public through the efforts of Austro-Hungarian citizens, the emperor of Austria having donated an operating table. The building has accommodations for fifty patients.

A Roof Camp.—A camp has been opened on the roof of the New York Throat, Nose and Lung Hospital on East Fifty-seventh Street for the treatment of tuberculosis patients. The camp is open on three sides and has ventilating skylights. It has a dining room, dormitory, dressing rooms and a shower bath.

Seizure of Ice Cream Cones.—More than 4,500,000 ice cream cones were seized by United States Marshal Henkel of New York, under the pure food law, on the ground that they contained boric acid and were detrimental to the public health. They were intended for shipment to Galveston, Tex. It has been found that ice cream cones are often composed largely of glue.

To Stop Smoke from Autos.—The amendment to the sanitary code relating to smoking automobiles has become operative. Drivers and owners of autos that throw out smoke are liable to arrest and fine. Seventy men of the sanitary squad were on duty when the amendment went into effect to see that it was obeyed. A slight smoke is overlooked or passed with only a warning.

Donations to Medical College.—Word from Dr. Royal S. Copeland, dean of the New York Homeopathic Medical College and Flower Hospital, states that $25,000 has recently been donated by the alumni and by the trustees for improvement of the laboratories and for changes in the college building. Several full-time salaried instructors in the laboratory branches are to be added.

A Sane Fourth in New York.—In accordance with the city ordinance forbidding the sale of fire crackers, fireworks, etc., these things were not on sale and the city had a quiet and orderly day. The health department had laid in the usual supply of tetanus antitoxin and sent out the usual directions for its use. Not only were there very few instances where the antitoxin was needed, but there was a great falling off in the number of fires. Last year there were 176 fires attributable to fireworks, while this year there were only 33. The damages from fires were only a little more than three thousand dollars this year against $20,000 for 1909.

NORTH CAROLINA

Tuberculosis Exhibit.—The National Tuberculosis Association recently held a very successful exhibit in Winston, creating much interest, the exhibit being inspected by several thousand people.

State Medical Board.—At the forty-eighth annual session of the State Board of Medical Examiners, at Wrightsville Beach, June 15-23, the board was reorganized with the election of Dr. Lewis B. McBrayer, Asheville, president for the ensuing year. Dr. Benjamin K. Hays was reelected secretary-treasurer.

Society Meeting.—The Sixth District Medical Association held its regular session at Raleigh recently. In addition to the instructive papers read, clinics were given at the Raleigh hospital. The following were elected officers: President, Dr. George W. Long, Graham; vice-president, Dr. Louis J. Picot, Raleigh; secretary, Dr. Charles A. Woodward, Durham.

Work of Hookworm Commission.—The North Carolina State Board of Health, working in conjunction with the Rockefeller hookworm commission, has appointed Dr. John A. Ferrall, special assistant secretary of the board for hookworm work. At a recent session, the state was divided into districts and the following physicians elected to make a thorough canvass of the state, working along anti-hookworm crusade lines: Dr. B. W. Page, Snead's Ferry; Dr. C. F. Strosnider, Wilmington; Dr. Claud L. Pridgen, Kinston.

Personal.—Dr. Benjamin K. Hays, Oxford, has been appointed local surgeon of the Southern Railway at Oxford.——Dr. David J. Hill, Lexington, has been appointed local surgeon of the Southern Railway at his home town.——Dr. Robert L. Payne, formerly of Lexington, has been appointed chief surgeon of the Norfolk & Southern Railway with headquarters at Norfolk, Va.——Dr. John Miller Faison, of Faison's, Duplin County, was nominated by the democratic party of the third district for Congress. Dr. Faison is a well known practicing physician, a prominent member of the State Medical Society, and his political recognition is appreciated by many friends in the profession.——Dr. John E. Ashcroft, Monroe, has been elected a member of the State Board of Health, vice Dr. James A. Burroughs, Asheville, deceased.

State Medical Society Meeting.—The fifty-seventh annual session of the Medical Society of the State of North Carolina was held at Wrightsville Beach June 21-23, under the presidency of Dr. Edward Jenner Wood, Wilmington, vice Dr. James A. Burroughs, president, deceased. The attendance was the largest in the society's history for a session at an extreme point in the state, more than 300 members being present. The session of 1911 will be held in Charlotte. The following officers were elected: Drs. Chalmers M. Van Poole, Salisbury, president; James V. McGougan, Fayetteville; William E. Warren, Williamston, and Lucius N. Glenn, Gastonia, vice-presidents; David A. Stanton, High Point, secretary; Herbert D. Walker, Elizabeth City, treasurer; James M. Templeton, Cary, orator; Samuel A. Stevens, Monroe, essayist; John M. Campbell, Morganton, leader of debate; Jacob F. Highsmith, Fayetteville, and J. Howell Way, Waynesville, delegates to American Medical Association, 1911-12. At one general session a conference on hookworm disease was held and a paper was read by Dr. Charles Wardell Stiles, scientific secretary of the Rockefeller hookworm commission. A night session was given over by the society to memorial exercises in honor of the thirty members who died during the year. Dr. J. Howell Way, of Waynesville, made an address on the life and character of Dr. James Anthony Burroughs, of Asheville, who was president of the society at the time of his death, and Dr. William Henry Harrison Cobb, of Goldsboro.

OHIO

Tuberculosis Hospital.—Construction has begun on the new tuberculosis hospital of the county infirmary at Columbus.

Public Health Bulletin.—The Board of Health of Columbus has begun publication and distribution of a bulletin to educate the public in sanitary and hygienic matters, following the plan of other cities.

College Merger.—It is reported that the Pulte Homeopathic College is to be merged with the Cleveland Homeopathic College. The consolidated school will be located at Cleveland and will be known as the Cleveland-Pulte Homeopathic Medical College.

Health Board News.—The mayor of Cleveland has appointed Drs. Edward F. Cushing and James E. Cogan on the health board of that city, and $40,000 has been voted to the board of health to complete the contagious disease hospital and to fight smallpox.

School for Medical Officers.—A school for medical officers of the Ohio National Guard, the first of its kind in the state, was held at Columbus in June. Major Joseph A. Hall, Cincinnati, acting surgeon-general of the guard, was the originator of the plan. The officers were instructed by Major Edward L. Munson, medical corps, U. S. army, and Major S. B. Taylor, medical corps, Ohio N. G. The meeting was attended by more than fifty members of the medical staff.

Personal.—Dr. Luther B. Turner, Columbus, has been elected district physician to succeed Dr. Lewis D. Wolfe, who resigned.——Dr. Arthur M. Harrison, Bowling Green, has been appointed assistant surgeon in the medical corps of the Ohio National Guard with rank of first lieutenant.——Dr. Robert H. Butler, Bellefontaine, has been appointed an assistant clinical instructor on the faculty of the Ohio-Miami Medical College, Cincinnati.——Dr. John C. Jones, a member of the board of education of Cleveland, and two daughters, are in Europe.——Dr. George M. Osborne, Portsmouth, has retired from practice.——Dr. Robert C. Longfellow, Toledo, in recognition of work done in laboratory pathology and bacteriology, has been given the degree of M.S. by St. John's University, Toledo.——Dr. John C. Fox, Cleveland, has been appointed physician at the City Hospital.

Changes at the University of Cincinnati.—At a meeting of the trustees of the University of Cincinnati, May 31, on the recommendation of President Dabney, a complete reorganization of the faculty of the Ohio-Miami Medical College (medical department of the University of Cincinnati) was adopted. It was found during the year just closed, the first year of the union of the Ohio and Miami colleges, that the faculty was much too large and consequently too unwieldy. The new plan provides for a clinical head and a didactic head in the more important departments, while in the smaller departments the two positions will be combined. The plan also provides for a salaried dean. The chiefs of the fundamental chairs of anatomy, physiology, pathology and chemistry will be on salary and will devote their entire time to the work. Dr. Paul G. Woolley, formerly of the University of Nebraska College of Medicine, is now the professor of pathology with Dr. William B. Wherry as assistant professor of bacteriology; Dr. Martin H. Fischer, of the Oakland (Cal.) College of Medicine and Surgery, has been secured as professor of physiology. A full-time professor in anatomy is still to be secured.——Dr. Charles E. Howard has been appointed receiving physician to the Cincinnati Hospital, vice Dr. Robert D. Mussey, resigned.——Dr. Rufus B. Hall has been appointed gynecologist to the Cincinnati Hospital, vice Dr. Charles L. Bonifield, resigned.

PENNSYLVANIA

Personal—Dr. H. J. Huber of Lancaster has located an office at Reading.——Dr. Leo Mundy of Wilkes-Barre will take charge, for several weeks, of the State Hospital at Holidaysburg, Blair county.

New Hospital at Wilkes-Barre.—It is planned to have a new hospital ready by November 1 at Wilkes-Barre. The physicians interested have empowered a committee to purchase a site at Hanover street and Carey avenue.

Scarlet Fever Prevents Outing of Insane.—The usual picnic at the State Hospital for the Insane which was to be held on July 4, was postponed because of scarlatina in a nurse. She was removed to the Municipal Hospital, Philadelphia, and a possible epidemic prevented.

A Prize Paper.—The State Pharmaceutical Association of Pennsylvania recently awarded its twenty-dollar gold prize to Dr. F. E. Stewart for his paper on "Patents and Trade-Marks," which was read before the Philadelphia branch of the American Pharmaceutical Association.

Sanatorium Receives Donation.—The Berks County Tuberculosis Society received two checks from wealthy philanthropic women of Reading. The money will be used toward the expense of a second building at the society's camp on Neversink Mountain for the accommodation of sixty additional patients.

Meeting of County Society.—The Blair County Medical Society met at Blair County Hospital, Altoona, June 28. Dr. W. M. Late Coplin, professor of pathology at Jefferson Medical College, delivered the chief address. The hospital was inspected and Dr. Sommers, its superintendent, gave a luncheon.

Tuberculosis Notes.—The Board of Health of Reading decided, June 27, to prohibit the use of public drinking cups.——The State Tuberculosis Exhibit was held in Wilkinsburg, near Pittsburg, June 28 to 30. Dr. John Bouse of the State Health Department, addressed a meeting on June 28 on tuberculosis in Pennsylvania.

Alumni Association Meets.—The Lehigh Valley Alumni Association of the Medico-Chirurgical College of Philadelphia met at Easton, June 26, and elected the following officers: President, Dr. F. E. Ward, Easton; vice-presidents, Drs. W. G. Tillman, Easton, Jacob Fraunfelter, Nazareth, and C. S. Kemper, Bethlehem; secretary, Dr. V. S. Messinger, Easton.

Williamsport Hospital Report.—In the annual report attention was called to the fact that the hospital has expended during the past decade for additions, new buildings and improvements $167,800, of which only about one-fourth was money secured from the state. The institution has grown to three times its former size and capacity, while its indebtedness for maintenance is less than one-seventh of what it was ten years ago. More patients were admitted last year than in any previous twelve months in its history, the average daily number being 92.2. The executive committee is composed of Dr. George D. Nutt, Dr. H. G. McCormick and Samuel N. Williams.

Philadelphia

Personal.—Dr. T. J. Ellinger, operated on for appendicitis July 9, is improving rapidly.——Dr. W. Wayne Babcock and Dr. and Mrs. Ellwood Matlack have sailed for Europe.

Physician in Serious Accident.—Dr. B. Franklin Stahl, while enroute to Maine in an automobile, was seriously injured by the turning over of the machine on a steep grade near Great Barrington, Mass. Mrs. Stahl was killed instantly. Dr. Stahl is lecturer on dietetics in the University of Pennsylvania, and wrote an article for the last Automobile Number of THE JOURNAL.

TEXAS

Personal—Dr. Whitfield Harral, medical director of the Southwestern Life Insurance Company, Dallas, was elected director of the exchange department of the American Life Convention at a meeting in Dallas, July 2.

Vaccination at El Paso.—On account of the recent epidemic of smallpox in northern Mexico, the health board of El Paso vaccinated over 5,000 persons and issued certificates of vaccination to over 12,000 people. The quarantine has been raised at El Paso and Juarez.

Society Meeting.—At a meeting of the Taylor County Medical Society held on June 27, in Abilene, Dr. Charles M. Rosser, Dallas, delivered an address on "Cancer of the Uterus." A dinner was given in honor of Dr. Rosser at the Hotel Grace. Covers were laid for thirty.

Laboratory of Preventive Medicine.—The board of regents of the University of Texas, at a meeting held May 31 at Galveston, approved the plans submitted by the faculty of the Medical Department for building and equipping a laboratory of preventive medicine and public health.

State Board Meeting.—At the meeting of the State Board of Medical Examiners, ending June 30, the following officers were elected: Dr. James D. Osborn, Cleburne, was reelected president; Dr. John D. Mitchell, Fort Worth, was reelected vice-president, and Dr. Robert H. McLeod, Palestine, was elected secretary-treasurer. Governor Campbell, the judges of the higher courts and the members of the board dined together at the Driskill Hotel, June 30.

College Commencement.—At the commencement exercises of the medical department of Fort Worth University, eleven physicians were graduated. Dr. Charles W. Stiles, U. S. P. H. and M.-H. Service delivered the principal address on "Hookworm and Typhoid Fever." Dr. Stiles said that it is through lack of sanitation that hookworm spreads and with it typhoid fever, which he claimed were the most loathsome and useless diseases known in medical annals. He said that we are dirtier than the Italian, that the Prussian equaled the American in conceit, but that no nation on earth equals us in filth. He declared that over 35,000 people die annually from typhoid fever in this country and our filth is responsible for it.

WISCONSIN

College Commencement.—At the seventeenth annual commencement exercises of the Wisconsin College of Physicians and Surgeon, Milwaukee, medical degrees were conferred on six graduates.

State Appointments.—The State Board of Control of Wisconsin Reformatory, Charitable and Penal Institutions has appointed the following physicians: Dr. Charles Gorst, superintendent of the Mendota Hospital for the Insane; Dr. W. A. Sherman, superintendent of the Northern Hospital for the Insane, Oshkosh; Dr. L. Rock Sleyster, physician to the State Reform Prison at Waupun; Dr. Alfred W. Wilmarth, superintendent, and Dr. Augustus L. Beier, assistant superintendent, Home for Feeble-Minded at Chippewa Falls, and Dr. John W. Coon, superintendent of the Tuberculosis Sanatorium at Wales.

Bequest to Medical School.—By the will of the late Dr. Byron Robinson of Chicago, of the class of '78, the Medical School of Wisconsin University receives his collection of books amounting to over 1,500 volumes. The library is unusually rich in early American medical treatises and old anatomic plates, besides modern works on anatomy, and on the history of medicine. A scholarship in anatomy worth $550 a year was also provided for in the bequest. The library is to be known as the Robinson-Waite Library in honor of the donor and his wife, Dr. Lucy Waite Robinson. The scholarship is to be known as the Byron Robinson scholarship in anatomy.

State Society Meets.—At the recent meeting of the State Medical Society of Wisconsin in Milwaukee the following officers were elected: President, Dr. Byron M. Caples, Waukesha; vice-presidents, Drs. John M. Dodd, Ashland; Theodore J. Redelings, Marinette, and Wilson Cunningham, Platteville; secretary, Dr. Charles S. Sheldon, Madison; assistant secretary, Dr. L. Rock Sleyster, Waupun, and treasurer, Dr. Sidney S. Hall, Ripon. To act on Council on Health and Public Instruction of American Medical Association, Dr. Charles R. Bardeen, Madison, vice W. B. Hill; delegate to National Legislative Council, Dr. Byron M. Caples, Madison; delegate to Council on Medical Education, A. M. A., Dr. M. P. Ravenel, Madison; delegates to A. M. A., Drs. Charles Sheldon, Madison, and A. H. Levings, Milwaukee; alternates, Drs. W. Cunningham and R. G. Sayle. The 1911 meeting will be held at Waukesha. Dr. Richard M. Pearce of the Carnegie laboratories, New York, and Dr. Joseph C. Bloodgood, Baltimore, were the guests of the society.——The first annual meeting of the Association of County Secretaries and Officers of the State Medical Society of Wisconsin was held in Milwaukee just prior to the meeting of the state society. There was a good attendance and many subjects relating to organization were discussed.

GENERAL NEWS

Printers' Tuberculosis Sanatorium.—At the meeting of the International Printing Pressmen and Assistants' Union at Columbus, provisions were made for the establishment of a national tuberculosis home for printers and pressmen at Hales' Springs, near Asheville, N. C.

Beriberi in the Philippines.—Dr. Victor G. Heiser, director of health in the Philippines, has evolved a plan which will make the Philippine Islands the first country in the east to wage a systematic war on beriberi. It is believed from recent studies that the disease is caused by a continued diet of polished rice, and Dr. Heiser proposes to abolish its use in the government workshops, prisons and other public institutions and substitute therefor red rice, containing phosphorus, the lack of which causes beriberi. An idea of the ravages of this disease in the Philippines may be gained from the fact that in the city of Manila alone the number of deaths from beriberi is 1,600 annually.

Prize Offered by International Dairy Federation for Essay on Milk.—The International Dairy Federation offers a prize of 500 francs ($100) for the best work on the comparative value of raw and cooked milk, to be submitted to the International Dairy Congress annually. The exact question is as follows: "To determine by latest experiments, made at least in part on man himself, the comparative nutritive value of raw milk and cooked milk (pasteurized, sterilized or desiccated). In case of an advantage in favor of raw milk, to determine the rôle that the enzymes of the milk play in nutrition." This prize is a permanent one, and is to be conferred at each of the international sessions of the Dairy Congress. Papers may be in French, German or English, and should be forwarded to the Secretary-General of the International Dairy Federation, 23 Rue David Desvachez, Brussels-Uccle, Belgium, not later than April 1, 1911.

Health in the Philippines.—The annual report of the Bureau of Health of the Philippine Islands—July 1. 1908, to June 30, 1909—contains a review of the work done by the department under Dr. Victor G. Heiser, Director of Health. The pamphlet is well illustrated and contains numerous charts, together with statistical tables covering the health and vital statistics from every angle, and the report shows that much effective work has been done [illegible] anitation and health of the islands. Manil [illegible] city, and much public improvement work [illegible] 'ere, a large portion of the report is taken up with what has been accomplished in that city. A new gravity water system, the supply for which is collected from an uninhabited watershed, has been so far completed that the water from it was turned on in November. In May the new sanitary sewer of the city was completed, but according to the quarterly report of the department for the last quarter of 1909 not a large number of house connections have yet been made, owing to the fact that many houses are of cheap construction and the owners cannot afford to install plumbing, the cost of which in many instances would equal or exceed the value of the property. The full benefit of the new sewer system on health conditions has not therefore been had. The bureau of public works sunk about 40 artesian wells and the provinces about as many more. The Baguio Hospital at Benguet, with a capacity of 44 patients, was opened in July. The modern reinforced concrete hospital at Bilibid, with a capacity of 376 patients, was put into use in February. The capacity of the Culion leper colony was increased to accommodate 1,900 lepers. It is found that leprosy is decreasing, so that one case in 2,800 of population is now discovered as against one in 2,000 previously found. Lepers are being collected in all the provinces and isolated in the Culion colony. A hookworm commission was placed in the field at Taytay and another at Las Piñas. Extensive drainage improvements were made on the San Lazaro Estate, making it possible to transfer over 1,000 persons who had previously occupied insanitary areas. In addition much routine work has been done by the department, including the suppression of a number of epidemics of cholera. It has been found in Manila that many cases have been reported as meningitis which on investigation proved to be cholera, and in many instances these were the foci from which subsequent outbreaks of cholera occurred. The report states that it is becoming more evident that by the observance of a few simple rules good health can be maintained with more certainty in the tropics than in temperate climates. Among the rules set out are the following: Be vaccinated; never drink water unless it has been boiled or distilled and never eat raw vegetables; thus you will avoid dysentery, cholera, typhoid fever and other intestinal diseases; fruit grown on trees may be eaten with impunity; do not use "patent medicines" or alcoholics; they are not necessary; sleep under a good mosquito net. Mosquitoes of the disease-carrying variety generally only fly at night. Otherwise observe the same hygienic rules that are applicable to temperate climates. The report contains studies of the different diseases and the methods employed in the different cities and provinces to combat them, the whole showing that conditions are constantly improving.

FOREIGN

Monument to Professor D'Urso.—During the annual session of the Sicilian Medical Association, held at Messina recently, a monument to its former president, G. D'Urso, a victim of the Messina earthquake, was unveiled in a public square.

Brazilian Neurologic Society.—At the meeting of the Brazillian Society of Neurology, Psychiatry and Legal Medicine, held at Rio de Janeiro, May 1, the following officers were elected: President, Prof. Juliano Moreira of Rio de Janeiro, director of the National Hospital for the Insane; vice-president, Dr. Carlos Eiras: *secretaries*, Dr. H. Roxo and Dr. Mario Pinheiro, and treasurer, Dr. A. Ramos.

Prize to Sanfelice for His Research on Cancer.—The Balbi-Valier prize of $600 was awarded this year to Prof. F. Sanfelice of Messina for his fifteen years of research on cancer which have resulted in the production of his cancer serum. (It was described in The Journal, June 26, 1909, page 2117.) The prize is awarded biennially to an Italian by the Venice Regio Istituto di Scienze, Lettere ed Arti for the greatest progress in medicine or surgery during the preceding two years.

Personal.—Dr. Wilhelm Roux, professor of anatomy at Halle, eminent for his contributions to embryology, celebrated his sixtieth birthday June 9, and a *Festschrift* in two volumes was presented to him.—Dr. E. A. Schäfer, professor of physiology in the University of Edinburgh, has received an honorary doctorate of medicine at the University of Berne, after lecturing at the university on "The Functions of the Pituitary Body."——Dr. Wolferstan Thomas, assistant lecturer in the Liverpool School of Tropical Medicine, has been appointed director of the new laboratories established in the state of Amazonas.——Surgeon E. L. Atkinson, R. N., is to accompany Capt. R. F. Scott and his Antarctic expedition, as doctor, bacteriologist and parasitologist.

Other Deaths in the Profession Abroad.—Dr. Edward Creswell Baber, M.B., L.R.C.P., M.R.C.S., linguist, scientist and laryngologist, a son of Dr. John Baber, of London, England, died in London May 14. He was noted for his studies of the thyroid in the lower animals, and as a laryngologist. He practiced in Brighton, where he was the founder of the Brighton Throat and Ear Hospital, and also in London.——Sir Francis Seymour Haden, F.R.C.S., of London, the famous etcher, and a noted surgeon in his day, died June 1 at Bramdean, Hampshire, aged 92.——William Rose, B.S., F.R.C.S., emeritus professor of surgery in King's College, author of works on surgery, died May 28 in London, aged 63.——William Henry Spencer, M.A., M.D., Cantab., M.R.C.P., Lond., formerly senior physician to the Royal Bristol Infirmary, died at Oxford, May 27, aged 73.——P. J. Pick, M.D., professor of dermatology at Prague until 1906, founder in 1869 of the *Archiv für Dermatologie und Syphilis*, died at Prague recently in his seventy-sixth year. The hundredth volume of his *Archiv*, which was dedicated to Caspari, contained a notable report from Pick on the later history of his syphilis patients. He aided in founding in 1898 the German Dermatologic Society and has been its perpetual president since, has contributed over 200 works on dermatology to the literature, and introduced iodoform into dermatologic practice as also the medicated gelatins.——Paulin Trolard, M.D., professor of anatomy in the Algiers College of Medicine.

LONDON LETTER

(From Our Regular Correspondent)

London, July 2, 1910.

A New Development in Library Work

The Royal Society of Medicine has instituted a new development by which its magnificent library may be useful to its fellows living in any part of the world. Short abstracts are prepared for them gratis, of papers and even of books, on any medical subject, and references to medical literature searched for and checked. This innovation has been warmly welcomed and grateful letters have been received from such remote places as the Chitral Valley, the Sudan and equatorial Africa, where for years men have had their work hindered by the inaccessibility of libraries. Some say that the work is done for them even better than if they had been in London, for they would probably not have been able to devote the many hours required for the research which the machinery of the library procures with a minimum of time and labor.

Relation of Medicine to Surgery

In recent years the development of the surgery of the internal organs—abdominal surgery, thoracic surgery and brain surgery—has involved a considerable encroachment by the surgeon on what was once the exclusive province of the physician and the process is by no means at an end. In a letter to the *Times* a layman advocates the handing over of appendicitis in particular and abdominal disease in general from the physician to the surgeon on the grounds that the latter's experience is more valuable, "he sees inside and outside," etc. This has called forth a reply from Sir Clifford Allbutt who points out that in the Hippocratean age there was no division of the art into medicine and surgery and Celsus recognized no such division. It was left for imperial Rome, with its formal ideas and medical slaves to initiate and for the feudal and ecclesiastical societies of the middle ages to extend and perpetuate the separation of the medical bookman from the medical workman. "The division between medicine and surgery was *not* a division of nature but an arrogant repudiation of the part of the hands in the work of the world." This fantastic separation of the thinker from the craftsman has produced, Sir Clifford says, enormous hindrances and ambiguities to which the divided practice in some cases of appendicitis calls attention. The gynecologists, who have seen the evil, have thrown over the convention and practice all the methods which the cases under their care require. The whole profession will have to follow suit and liberate physicians for the complete performance of their own responsibilities. These contentions do not question the need of specialism. This is another problem. One physician will make himself completely efficient in abdominal disease; another in diseases of the pelvis; another of the chest, and so on; while some will prefer diseases in which, if surgery is not yet applicable, the most excellent education of the hand will be maintained by chemical and other manipulations. There is no longer place for the mere academic or book-doctor. For this integration of medicine and the healing of its crippling schism, Sir Clifford recommends the amalgamation of the Colleges of Physicians and Surgeons into an Academy of Medicine.

Medical Missionaries

The important part played by physicians in missionary work was shown at the World Missionary Conference which has recently taken place at Edinburgh, where it was freely admitted that medicine was a most powerful auxiliary to doctrinal teaching. Of the 5,522 Protestant regular missionaries now at work in the world 641 men and 341 women are medically trained and duly qualified. There are 550 hospitals and 1,024 dispensaries employed in missionary work. On the question of the training of medical missionaries there was a unanimity of opinion that the medical missionary could not be too highly trained in his profession. Candidates were advised to take postgraduate study in such subjects as tropical diseases and ophthalmology. It was further suggested that practical experience of hospital work as a resident, either at home or on the field, was desirable before undertaking the duties of a medical mission station for the first time.

Artificial Teeth the Cause of Death

A curious case of death the remote result of a motor accident has been the subject of a coroner's inquest. A woman while cycling in December, 1908, was knocked down and run over by a motor car. Her skull and clavicle were fractured. She was wearing a plate bearing four artificial teeth. This was missing from her mouth but two teeth and part of the plate were found in the car. What had become of the others was a mystery. She was discharged from hospital in January, 1909, and her recovery was so complete that she married in the following November. But ever since the accident she complained of throat symptoms. Three weeks ago she returned to the hospital, where she died this week. The postmortem examination showed in the esophagus the missing piece of the plate with the two teeth attached, fastened deep in the tissues by its gold hook. Round this an abscess had developed which caused death.

Ophthalmology at Oxford

Oxford University was the first body in this country to grant a diploma in ophthalmology. Candidates must have taken courses of instruction in the university on the anatomy, physiology and diseases of the eye. The course of anatomy and physiology extends over two months and that on diseases of the eye over three months. Another feature of Oxford is the Congress of Ophthalmic Surgeons which is held annually. This year it will assemble at Keble College, July 20 to 22. The special feature of the congress will be operations for cataract and glaucoma, which will be performed by some of the most eminent specialists, among others, Professor Lagrange of Bordeaux, Professor Holth of Kristiania, Professor Heine of Kiel, and Colonel Herbert of Nottingham, who will each perform his own operation for glaucoma. Sir Anderson Critchett will operate for cataract and Major Gidney will perform the intracapsular cataract extraction practiced by Major Smith. A novel feature of the congress is that there will be no papers and discussion, but a series of demonstrations and exhibitions.

Visit of American Surgeons to England

A party of the members of the American Society of Clinical Surgery are making a tour of the principal surgical clinics of this country. They include Samuel Alexander, Kansas City; Willard Bartlett, St. Louis; Arthur D. Bevan, Frank Billings, M. L. Harris, J. B. Murphy and L. L. MacArthur, Chicago; Joseph A. Blake, George E. Brewer, Ellsworth Eliot, L. W. Hotchkiss and George Woolsey, New York; Ernest A. Codman, F. B. Lund, J. C. Munro and C. A. Porter, Boston; Gwilym G. Davis, C. H. Frazier, J. H. Gibbon, J. T. Hutchinson, Edward Martin, R. H. Harte and R. G. Le Conte, Philadelphia; John M. T. Finney and Harvey Cushing, Baltimore; Charles H. Mayo, Rochester, and Emmet Rixford, San Francisco. The tour in London includes visits to the following hospitals: St. Thomas's, King's, Middlesex, Guy's, St. Bartholomew's, London Temperance, National Hospital for Epilepsy. Mr. Makins, Sir Watson Cheyne, Mr. Bland Sutton, Mr. Arbuthnot Lane, Mr. Lockwood, Mr. H. Patterson and Sir Victor Horsley are doing the honors at the respective clinics. The Frimley Sanatorium for Consumptives and the Museum of the Royal College of Surgeons will also be inspected. From London the party will go to Edinburgh where they will visit the Royal Hospital Infirmary and the Hospital for Sick Children and be received by Mr. Alexis Thomson and Mr. Harold Stiles. Thence they will proceed to Newcastle and Leeds to visit the clinics of Mr. Rutherford Morison and Mr. Moynihan, and finally to Liverpool to the clinic of Mr. Robert Jones.

PARIS LETTER

(From Our Regular Correspondent)

Paris, July 1, 1910.

Against Infant Mortality

The Ligue Contre la Mortalité Infantile has just held its first general assembly under the presidency of M. Mirman, director of public charities and hygiene at the Ministry of the Interior. Dr. Aviragnet, secretary of the society, read the general report, from which it appears that infants' consultations have been created within several years in 61 departments and are in regular operation in more than 380 localities. Dr. Aviragnet demanded that besides commercial milk there should be a specially controlled milk for infants and invalids, as in certain foreign countries. M. Mirman delivered an address on the means at the disposal of the government to combat infant mortality. He indicated that the Théophile Roussel law, which established medical supervision over children entrusted to hired nurses, affects annually only 170,000 children under 2 years. Since the births amount to almost 800,000 a year a great many young children are not under any medical supervision. The mortality of infants under a year increased in Paris from 1887 to 1891 to 299 per thousand. This rate diminished between 1901 and 1905 to 156 per thousand, that is to say, it decreased about 50 per cent. The same conditions are reported in other French cities having more than 30,000 inhabitants. In spite of this decrease infantile gastroenteritis every year carries off tens of thousands of children.

The Reorganization of the Hospitals

Though France has the incontestable credit of founding charitable institutions at a very early period, as is proved by the old hospitals such as the Hôpital-Dieu at Paris, that of Lyons, that of Rheims, etc., at present most of our hospital buildings do not meet the demands of modern medicine and surgery. Accordingly the municipality of Lyons has decided to construct a model hospital for 1,200 patients, which is to contain also all the clinics of the Lyons college of medicine. Before executing this work the municipality sent a mission to study the German and Danish hospitals. M. Edouard Herriot, mayor of Lyons and member of the superior council of public charities, who headed the mission, has just made public his impressions on this journey. He learned much in Germany and became convinced of the archaic character of the French hospital organization and of the necessity for its complete reform. M. Herriot insists particularly on the fact that scarcely any French hospitals have enough isolation rooms, so that it is not rare to see the delirium of dying patients disturbing the physical and moral repose of their companions.

It is important, moreover, that the construction of a modern hospital should not be left to the architect, whose main concern is for beauty of line. The Virchow Hospital at Berlin, where so much progress has been realized, has suffered from this defect. The principles of construction should have been laid down by the physicians and surgeons. If at Paris the old Cochin Hospital possesses to-day a perfectly organized surgical service it is because Professor Quénu was able to collaborate constantly in the construction of the building for this service, which he directs.

A Proposed Remedy for Depopulation

Dr. Lannelongue, a professor at the Paris college of medicine and a senator, has just laid before the bureau of the senate a bill directed against depopulation. Among the first causes of the evil Dr. Lannelongue mentions prolonged or perpetual celibacy, late marriage, the excessive tendency to seek official life, the lack of testamentary liberty, the precarious situation of the salaried official, rural emigration, etc. The slenderness of our birth-rate does not come, as one might believe, from purely physiologic causes. Statistics show that sterility has remained stationary; it amounted to 18 per cent. in 1856, and did not exceed 17 per cent. in 1891. If the birth-rate has diminished, it is not because the proportion of childless families has increased, but because the number of children in fecund families has diminished. The factors of weakness and of decadence against which it is necessary to strive for the conservation of the race and the future of the nation are the results of a more or less voluntary and deliberate limitation of the fertility of women which reduces the number of children to the minimum.

Dr. Lannelongue proposes a whole series of measures to combat depopulation. In the first place he proposes to lay supplementary military obligations from the age of 29 on celibates, who, since they do not fulfil the duty which they owe to the state of bringing children into the world, should have special obligations toward the national defense, from which married men and the fathers of families should be free. A proposition which will, no doubt, be considered audacious is that of requiring marriage of civil officials above the age of 25. Dr. Lannelongue, moreover, proposes certain pecuniary advantages during active service and at retirement for the benefit of civil employees who have not less than three living children. Finally, he proposes a modification of the civil code so as to give the father of a family absolute liberty in disposing of his patrimony, which will have the effect of dispelling the fear, too frequent among parents, of having to let their fortune be parceled out among a great number of children. The absolute right of testamentary disposition would, moreover, have the advantage of habituating young people to rely on their own intelligence and activities for their means of existence.

Election of Professor Roger to the Academy of Medicine

In its session of June 28 the Académie de Médecine elected a titular member in the section of pathologic anatomy in place of Dr. Malassez, who died last September. Dr. Henri Roger, professor of experimental pathology at the Paris college of medicine and physician of the Hôpital de la Charité, was elected.

BERLIN LETTER

(From Our Regular Correspondent)

Berlin, June 23, 1910.

Centennial of the Berlin University

The program for the celebration of the university centennial is now settled. October 10 at 6 p. m. divine service will be held in the cathedral, at 8 p. m. a reception at the university and, following that, a torchlight procession. October 11 the first celebration will take place in the new aula and at noon there will be a banquet; October 12 a second celebration in the new aula, in the afternoon a garden festival in the exposition park and in the evening a "Kommers" of the student body in the exposition hall of the zoologic garden.

Sanitary Reports on German Southwest Africa

The first report of the experiences collected in regard to the military sanitation in German Southwest Africa from 1904 to 1907, during the Herero and Hottentot campaign is at hand, prepared by the commander of our defense army. In this report there are included communications regarding the sanitary corps, the organization of the sanitary service, the sanitary equipment and the aid of the sick. Among about 21,000 soldiers employed in the protective service, the sanitary corps consisted of 922 men, of whom 187 were sanitary officers. There was one physician to 120 men. Of the entire sanitary corps 41, or 4.7 per cent., died. Of these 12 fell in battle (5 sanitary officers and 7 assistants). In the sanitary service on the field a field hospital was erected only in large undertakings. Even the erection of a division hospital was generally impracticable on account of the peculiar style of fighting which endangered particularly those carrying the wounded. Clothing with corduroy and khaki gave good service. The entire load of each foot soldier was about 52 pounds (26 kg). The food was often unsatisfactory. Many cases of scurvy necessitated the issue of chocolate, fruit juices, citric acid and condensed milk. Alcohol was often necessary on cold nights in the face of the enemy, while it was also evident that the effectiveness of the troops and their resistance to disease was not in the least diminished by involuntary abstinence from alcohol. Bathing was sometimes impossible for weeks on account of want of water. Clarification with alum and subsequent boiling sufficed for the purification of drinking water. Among the prisoners, a total of 15,000 Hereros and 9,000 Hottentots, infectious diseases were rife, especially dysentery, typhoid and syphilis (in the prison at Karibid 70 per cent. were syphilitic) and formed a constant danger to the troops. The care of the sick was the source of great difficulties; severely wounded patients with high fever had often to be transported on horses to which they were bound with thongs. It was necessary for the severely sick to remain often for days and weeks in ox carts.

Personal

Professor Krehl has unexpectedly declined the call to Leipsic as successor of Curschmann. It is confidently to be expected that at the next vacancy in a large university city (which may be Munich) Krehl will again be taken into consideration as the suitable successor.

Professor Döderlein of Munich has received a call for the position of Professor Olshausen. Döderlein was, as I have reported to you a few weeks ago, formerly on the appointment list of the faculty of the university of this city. It is doubtful whether he will accept the call; this depends on the action of the Munich authorities in providing the new building which he desires for his clinic. The Munich medical faculty has addressed a petition to the ministry to this effect and also the students made a visit to the department asking that Döderlein be retained in the university. It is to be expected that the Bavarian government will accept the ultimatum of Döderlein, and that the latter will remain in Munich. In that case the Prussian government will probably call Professor Hofmeier of Würzburg whom the faculty of the Berlin university nominated to the first place after the refusal of Krönig. As successor of the recently deceased Professor Zuckerkandl of Vienna, Professor Rabl of Leipsic was chosen, but declined.

Meeting of Tuberculosis Physicians in Carlsruhe

Early in June the seventh convention of the German tuberculosis physicians occurred at Carlsruhe and the proceedings were interesting with reference to the diagnosis, prophylaxis, and treatment of tuberculosis. Professor Feer, director of the Heidelberg pediatric clinic, reported his experience with the cutaneous and ocular tuberculin test; 2,000 children in his clinic were submitted to the von Pirquet test, in 86.7 per cent. of whom there was no suspicion of tuberculosis, in 4.8 per cent. there was suspicion, and 8.5 per cent. were clinically evidently tuberculous. In the first six months of life, 1.7 per cent. reacted positively, in the second six months, 7.3 per cent. Of 1,732 non-suspects none reacted positively up to six months of age: from six to twelve months, 3.4 per cent.; 1 to 2 years, 6 per cent.; 2 to 3 years, 11 per cent.; 3 to 5 years, 17 per cent.; 5 to 7 years, 22 per cent.; 7 to 10 years, 29 per cent.; 10 to 15 years, 38 per cent. According to Feer, the Pirquet test is specific, but with a very irritable skin the reaction may be simulated. In many cases of inactive tuberculosis, especially in children over 5 years of age, the reaction was positive at the second trial. Active tuberculosis very seldom gives a negative result with the cutaneous test. Feer never observed injurious effects. The positive result loses its value after the third to fourth year of life as it often occurs in the inactive form. On the other hand, the negative result is very significant. The ocular test was applied in 271 cases, only a single instillation of a drop of 1 per cent. of old tuberculin being made. Of 253 clinically tuberculous women a positive reaction was found in 22 per cent. of the 92 who showed a positive result by the Pirquet test. In 5 of the 101 positive ocular reactions severe conjunctivitis was observed. Dr. Roepke of Melsungen recommends an ambulant tuberculin treatment for patients after the usually too short sanatorium treatment. In his opinion the tuberculin preparations afford the only specifically active remedies. He recommends the gradually progressive method avoiding reactions as far as possible. In this way the occupation is as a rule not disturbed. Dr. Koppert in the sanatorium treatment favors rest and protection for the patients at first, especially by treatment in recumbency, but later he introduces systematic exercises for the increase of the resisting power and self-confidence of the patient. By confinement to bed a weakening of the entire musculature of the body is easily produced: this inconvenience is mitigated or removed by walking exercises, systematic muscular work, etc. The period of employment must not exceed 2 to 4 hours daily. Dr. Junker also recommends a systematic employment in the popular sanatoria, especially by garden work and agricultural labor and by housework for women. Professor Starck (Carlsruhe) treated the subject of tuberculosis and pregnancy. Among about 65,000 pregnant women 1.6 per cent. were found tuberculous. Here, however, only severe cases appear to have attracted attention and the mild cases presented no striking symptoms, so that it may be concluded that very light cases are little influenced by pregnancy. He found in his material that about one-fourth of all the cases of tuberculous pregnant women first showed evident symptoms during pregnancy. Severe forms become aggravated in the course of a pregnancy without exception, but mild forms often bear it remarkably well, although the prognosis must always be uncertain. Pulmonary tuberculosis complicated by laryngeal tuberculosis during pregnancy render the prognosis still more unfavorable. As to the influence of tuberculosis on the pregnancy, it appears that in general abortions are not more common than among non-tuberculous women. Premature birth occurs, however, oftener in cases of severe tuberculosis. The influence of the mother's tuberculosis on the fetus may be exerted in three ways, by intrauterine infection (which is very rare), by the weakened constitution of the prematurely born child, and by the inherited predisposition. The therapy of tuberculous pregnancy is essentially prophylactic. Tuberculous girls must be warned against marriage. After recovery from tuberculosis permission to marry must be granted only after the expiration of from two to three years. When tuberculosis occurs in a married woman, conception must be prevented if possible. Starck does not advise the induction of premature labor in a tuberculous pregnant woman, because he considers it as injurious for the tuberculous patient as delivery at full term. On the other hand, the earliest possible abortion has a favorable influence on the course of the tuberculosis. The complication with laryngeal tuberculosis is an unconditional indication for abortion in the first few months.

VIENNA LETTER

(From Our Regular Correspondent)

Vienna, June 23, 1910.

The Tuberculous Patient and the Austrian Law

The increasing vigilance with which the public is watching the spread and prevention of tuberculosis has caused a physician to compile the present regulations of the Austrian law, in regard to tuberculosis. The law justifies the breaking of an engagement of marriage by either party if the other is found out to suffer from active tuberculosis. If, however, tuberculosis becomes manifest or recognized only after the wedding the marriage is valid. On the principle that damages can be claimed from the party responsible for the loss, landlords are entitled to have the flat from which a tuberculous patient has moved disinfected at the expense of the patient. Public spitting may be, and has been prohibited, and a fine, sometimes very high, may be imposed if the law is transgressed. Private corporations have sometimes obtained damages on this ground. Children suffering from tuberculosis are not allowed to visit public schools, except for examinations. A movement is now on foot to establish special classes for tuberculous children, in spite of medical remonstrations against the necessity of keeping such children in school at all. A tuberculous teacher is strictly forbidden to continue his occupation. A tuberculous prisoner may claim postponement of his term of imprisonment, and a recruit is entitled to a leave of one to three years, or, if after his twenty-fourth year, he still is suffering from demonstrable illness, he has to be dismissed. Interesting disputes under the claim of workmen's compensation have been brought to the courts when laborers have contracted the disease while engaged in certain kinds of work under conditions favorable to infection. As a rule, the attitude of the courts of law is not very favorable in this respect to the employed persons. The attempt has been made, but as yet unsuccessfully, to make tuberculosis a notifiable disease, according to the terms of the public health bill now under consideration, and to provide that in order to obtain the marriage license, both parties shall produce a certificate of health, especially of freedom from tuberculosis. This summary of legal provisions bearing on disease is, of course, not exhaustive, but only those that are most likely to occur in every-day life.

MANILA LETTER

(From Our Regular Correspondent)

Manila, May 31, 1910.

Infant Mortality

Widespread interest is shown in Manila in the present campaign against the existing high mortality among infants and children. It is not uncommon to notice in the daily health reports of Manila such statistics as these: Total deaths for the day 25, infants 18, or total deaths 15, infants 11. The chief cause of this high death rate is universally considered to be improper environment, care and feeding. Both Filipino and American physicians are actively engaged in combating such a disproportionate mortality of babies. Among the Filipino physicians Dr. Calderon, recent delegate to the International Congress of Tuberculosis at Washington, is the most actively engaged in this work. The Bureau of Health and the Manila Medical Society are also lending their aid. Appeals are frequently made through the daily press and the public are quite well aware of the condition of affairs. This, however, is of no particular significance to the vast majority of Filipinos, who are quite accustomed to it. In fact in the old days before American sanitation was established the death-rate among the babies was, if we can trust the meager statistics available and the memory of the oldest residents, even much greater than it is to-day. Most of the burden of this work naturally falls on the Americans and the few more intelligent Filipinos; since, for reasons stated above, the great mass of the population can hardly be expected to aid, and the foreign residents (English, German and Spanish) who remain more or less segregated and who as a rule have no interest in the welfare of the islands except in a commercial sense, have not proved very charitable.

If the vital statistics of the Bureau of Health of the Philippine Islands be studied it will be seen that, but for the great mortality of infants and children, the health of Manila will compare favorably with that of any American city of like size. There are fewer deaths from pneumonia, diabetes, typhoid and heart disease than is the rule in American cities of 250,000 inhabitants. The sanitary conditions are excellent. Pure water is to be had at a slight cost and the climatic conditions are never excessive. In view of these conditions the medical profession of Manila has set itself to the task of looking into the conditions obtaining in the home of the average Filipino mother and to ascertain the cause for such a high death-rate among the babies.

Accordingly the American Association for Study and Prevention of Infant Mortality was organized and held its first meeting last November. At the close of the four days' session resolutions were adopted stating that the present high rate of infant mortality is due to inherent debility or disease, improper environment and care, improper feeding and communicable diseases, and is to a high degree preventable; that the breast feeding of infants is, when possible, the only proper method; that the reporting of all communicable diseases, especially of those commonest in society, to health boards, should be compulsory; and that the scientific instruction of the young in practical hygiene and sanitation, and of mothers in the care and rearing of infants is an important duty resting chiefly on physicians, sociologists, school authorities and boards of health. The Bureau of Health and prominent native physicians and many Americans have been making efforts to supply proper nourishment in the homes of the classes through the Gota de Leche, an organization which is taking charge of most of the charities for the relief of the babies.

Inspection of Meats

The Bureau of Health and the Bureau of Agriculture have recently joined forces in instituting a rigid inspection of all meats entering Manila from a foreign country. The two bureaus are to cooperate in this inspection and the Bureau of Science has offered to analyze any suspicious specimens sent to it by the meat inspectors. Live animals shipped into the islands for food are also subjected to a rigid inspection before being allowed to land and are held in quarantine on the least provocation. Thus by a system of double inspection, one abroad and one before landing, sound meat is practically assured the people of Manila.

Meeting of Far Eastern Association of Tropical Medicine

The first biennial meeting of the Far Eastern Association of Tropical Medicine was held at Manila, P. I., the first week in April. [As noted in The Journal, May 18.—Ed.] The congress was attended by seventy six medical men engaged in professional work in the far east, including the official delegates from the governments of India, Ceylon, Siam, Netherlands, India, the Federated Malay States, the Straits Settlements, Hongkong, the Philippine Islands, Tsingtau and Japan. There were eight scientific meetings. With the exception of the final meeting, which was held at Babuio, the new summer capital of the islands, all the meetings of the congress were held in the administration building of the new General Hospital of Manila.

The general run of the papers was good and most of them were of a high standard.

Among those of more than a local or more than a tropical interest may be mentioned one by Dr. S. Purdy of Auckland, New Zealand, on "Flies and Fleas as Factors in the Dissemination of Disease." From his experience in India and Egypt he is led to place particular emphasis on the danger of flies, especially in disseminating cholera and typhoid fever. He spoke favorably of the effects of petroleum in killing flies in the larval stage.

In connection with the subject of the notification of diseases in Manila a valuable paper was read by Dr. Maclachlan of the Bureau of Health and Dr. Andrews of the Bureau of Science, entitled "Studies in Infantile Mortality." It was a record of a verification of the causes of death as registered at the ordinary registry offices. The deaths of ninety-two infants under one year of age were verified, as to the cause of death, by post-mortem examination. It was found that out of the ninety-two cases, taken at random, 47 per cent. were due to infantile beriberi. Despite any doubt as to the validity of the diagnosis in any of these cases, it would still seem evident from the statistics furnished that the greater portion of the deaths of infants in Manila, as in most of the cities of Siam, India, Japan, etc., is due to digestive troubles arising from improper feeding. It was further shown that the deaths of children under 1 year in the Philippines amounts to 48.8 per cent. of the total deaths recorded.

The largest attendance occurred on Friday, when the subject of beriberi was brought up for discussion. This is a topic of widespread medical interest in the far East, especially in the tropics. Papers were read on "The Cause of Beriberi," by Dr. J. de Haan, delegate from Netherlands, India, and Dr. H. Fraser, delegate from the Federated Malay States; on "Beriberi in Siam," by Dr. Highet, delegate from the Government of Siam; on "Food and Metabolism in Beriberi," by Dr. Hans Aron; and on "The Etiology of Beriberi," by Dr. E. Musgrave of the Bureau of Science. An interesting point about these papers is that from each of those districts evidence was brought forward to show that beriberi is closely associated with the continuous consumption of white polished rice as the staple article of diet. In reviewing past work on beriberi, Dr. de Haan showed that the idea of this disease being caused by a bacterium is untenable, that it is a food disease, and that in Netherlands, India, it had been found that it could be kept very much in abeyance by adding to the white rice diet a form of green pea which is called "*Katchang idj-ju.*" The indications are that unpolished rice or rice milled by the native crude method does not give rise to beriberi. The explanation is, that in polishing rice the outermost layer of cells, which contain most of the fat and phosphorus, is polished off and it is the lack of these constituents which gives rise to beriberi.

At the concluding meeting of the association, Dr. Clark, who is the Medical Officer of Health of Hongkong, extended a cordial invitation from the government of Hongkong to the Far Eastern Association of Tropical Medicine to meet there in 1912. The invitation was endorsed not only by the government but also by the British colonial office. The association accepted the invitation with acclamation. Dr. Atkinson of Hongkong was elected president. The following vice-presidents were elected: Sir A. Perry (Colombo), Dr. de Haan (Netherlands, India), Dr. Ellis (Straits Settlements), Dr. Highet (Siam), and Dr. Shibayama (Japan).

Miscellany

Cardiac and Respiratory Failure Associated with Engorgement of the Thyroid.—In a discussion on lymphatism (*Proc. Roy. Soc. Med.*, March, 1910) Mr. Carter Braine reported a case of cardiac and respiratory failure, during an operation for the removal of an abdominal tumor. The failure seemed to be due to an engorgement of the thyroid gland, which previous to the operation had seemed to be normal. The patient was an emaciated woman, aged 24, extremely nervous and with a rapid pulse. Ethyl chlorid followed by ether was used. The patient was placed in the Trendelenburg position and the abdomen opened. The operator requested that the patient be relaxed a little further on account of rigidity of the recti; at this time the pupils were dilated and a light-reflex was present. On pushing the anesthesia a little further the pulse became feeble, the pupils were still very large and a doubtful corneal reflex was present. There had been no traction on the abdominal contents. Respirations became very shallow; the anesthetic was stopped and chest compressions employed to assist respiration. Breathing ceased, however. There had been no cyanosis, no stertor; the color was ash-grey and the pulse imperceptible at the wrist. Artificial respiration and oxygen were employed and persevered in, although the patient was considered by all present to be dead. The tongue was well forward and had given no trouble. It was then noticed that the thyroid was swollen, the two lateral lobes and the isthmus being well-marked. The anesthetist was absolutely certain that this swelling was not present before the anesthetic was commenced. The patient had been removed to the floor to facilitate the employment of artificial respiration. Believing that the inability to restore the respiration might be due to the swelling of the gland the head was raised from the floor and slightly flexed on the sternum and artificial respiration continued in this position. In a few minutes the pupils commenced to contract, a thready pulse returned, and respiration became reestablished. Strychnin was given, the patient placed on the table and the operation completed under light anesthesia with the patient in the horizontal position. The patient was returned to her bed with color and pulse good and no trace of the swelling of the thyroid could be discovered. Though perhaps rare, this possibility should be kept in mind in respiratory and cardiac failure during anesthesia, and it should be borne in mind that in status lymphaticus the thymus might also become engorged, giving rise to reflex cardiac inhibition or respiratory stasis.

Variation in the Inherent Phagocytic Power of Leucocytes.—The opsonic index, according to E. E. Glynn and G. L. Cox (*Jour. Path. and Bacteriol.*, 1909, xiv, 90), as determined by the Wright technic, does not necessarily represent the true index of the power of phagocytic response of the blood of any given individual. In determining the opsonic index of a given patient's blood, Wright and his school do not take into account the possibility that there may be differences in the phagocytic power of various strains of leucocytes, as well as in the different types of leucocytes themselves. Wright himself said, "It clearly emerges that the phagocytic count is uninfluenced by the corpuscle employed. . . . It will make it clear that we may take the opsonic index of any blood as an index of the patient's power of phagocytic response." From their observations on human beings, Glynn and Cox are led to take exceptions to this doctrine. They find that both serum and leucocytes are subject to change, so that both must be taken into consideration in estimating the extent of phagocytosis of a given blood. They claim to have shown that "there may be a marked and often very constant difference in the phagocytic capacity of various strains of polymorphonuclear leucocytes. These differences may be apparent not only in pathologic blood, but also in normal blood. The opsonic index does not necessarily coincide with the index obtained by mixing a person's own leucocytes with his own serum. The extent of the phagocytosis obtained when washed leucocytes and serum from the same individual are incubated together can be correctly estimated by separately measuring the proportions due to the serum and washed leucocytes respectively. The inherent phagocytic power of the leucocytes of different individuals towards bacteria may tend to be constantly below a given standard, not only in disease but to a lesser extent in health. The phagocytic power of different leucocytes is subject to variations in the same individual which are at least as marked as those in the amount of opsonin (in undiluted serum), but there is no evidence that the variations are specific in the uninfected."

Mission Hospital Patients in Turkey.—Dr. C. D. Ussher, a medical missionary in Van, Turkey, writes that people in America would undoubtedly flee the dispensary connected with his hospital if they should see the patients. He says: "Picture them brought in among the crowd; smallpox cases in every stage, papules, vesicles, pustules and scabs; famine, scarlet fever, diphtheria, measles and whooping-cough. If you talk to the friends about microbes and infection, many either look at you nonplussed or assure you that there are no microbes on them, they had a bath a month or two ago or 'last Easter.' Those whose friends are able to care for them properly are sent home and those most needy are sent to the hospital if there is room for them. Yes, smallpox, scarlet fever, typhus, typhoid, and all are sent to our one and only hospital, and it takes much labor and expense in washing, bathing and disinfecting to prevent infection of others." The hospital is a three-story building, 50 by 70 feet, with four general wards and nine private wards, one of which with two beds is used for contagious diseases when cases are few.

Cradling in Treatment of Strangulated Hernia.—In a communication in the *Progrès Médical*, March 19, 1910, M. de la Roquette refers to a case recently reported in which strangulated eventration became spontaneously reduced as the patient's head was kept constantly lower than the pelvis. He then reports a case from his own experience in which an irreducible strangulated hernia gave rise to such threatening symptoms that the patient was taken at once to the nearest hospital, but this was miles away and the patient had to be carried down in the native (Chinese) litter which is suspended at the head and foot from the center of a crossbar borne on the shoulders of two men. The continuous swaying resulted in the spontaneous reduction of the hernia in this case, and he suggests that some such cradling device might be systematically applied in treatment of strangulated hernia.

Aneurism of the Vertebral Artery and Celiac Axis.—A man, aged 57, had complained of neuralgic headache at intervals for six years (Longcope: *Proc. Path. Soc., Philadelphia*, February, 1910). Six days before admission to hospital the pain became worse and the patient fell unconscious, remaining so for thirty minutes. When he recovered consciousness his right foot was paralyzed, and on admission to the hospital he had fever, retraction of the head, paralysis of the right foot and delirium. Six lumbar punctures were performed and pure blood was obtained each time. The patient died of pneumonia. Autopsy revealed a ruptured aneurism of the vertebral artery. In the celiac axis there was a nodule which was thought to be a thrombus, but which when dissected away was found to be a true dissecting aneurism.

Marriages

Edward Patera, M.D., to Miss Jane Smyth, both of Chicago, July 2.

Joseph Isaac Kemler, M.D., to Miss Rebecca Macht, at Baltimore, June 29.

J. Page Strong, M.D., to Miss Camilla Lucille Gordon, at Baltimore, June 29.

William Harris, M.D., to Miss Julia L. Shrotz, both of Philadelphia, June 28.

John A. C. Tull, M.D., Atlantic City, N. J., to Miss Lyons at Guelph, Canada, recently.

Walter F. Nuzum, M.D., Spokane, Wash., to Miss Martha Kilian of Baraboo, Wis., June 23.

Thomas G. McLin, M.D., to Miss Nena E. Inskeep, both of Fairfield, Ill., at Chicago, June 24.

Franklin Harold Crail, M.D., East Las Vegas, N. M., to Miss Laura Hallock of Denver, June 28.

Luther Gould Dearborn, Jr., M.D., Derry, N. H., to Miss Luella Fitch of Cambridge, Mass., June 8.

Moses P. Rucker, M.D., Bedford City, Va., to Miss Mary P. Williams of Fredericksburg, Va., June 27.

William Richard Arthur, M.D., Greene, Iowa, to Miss Hazel Claire Loomis of Des Moines, June 30.

Kuno Herbert Struck, M.D., Davenport, Iowa, to Miss Norma Little Petersen of Iowa City, June 23.

Farquhard Campbell, M.D., to Miss Maude Barbour, both of Kansas City, Kan., at Leavenworth, Kan., June 25.

Jesse Newton Hill, M.D., Osawatomie, Kan., to Miss Minnie Grace Kinman of Pleasant Hill, Mo., June 23.

George M. Jennings, M.D., Missoula, Mont., to Miss Sabra Swenson of New London, Minn., in Minneapolis, June 8.

William Henry Donovan, M.D., Iowa City, Iowa, to Miss Josephine M. Barry of Monticello, Iowa, at Iowa City, June 22.

Deaths

Henry Harris Aubrey Beach, M.D. Harvard Medical School, Boston, 1868; a member of the Massachusetts Medical Society; Boston Society for Medical Science, the Society for Medical Improvement, and the Society for Medical Observation; formerly demonstrator of anatomy and instructor and lecturer on surgery in Harvard Medical School; for two years associate editor of the Boston Medical and Surgical Journal; died at his home, June 28, aged 66.

Clement Bloch, M.D. University of Koenigsberg, Germany, 1890; a member of the German Medical Society; for five years head physician of the Montefiore Home; visiting physician to the Polyclinic Hospital and Mount Sinai Hospital, and physician to Sydenham Hospital, New York City; died at his home in that city, July 3, from heart disease, aged 46.

Charles Zellhoefer, M.D. New York University Medical College, New York City, 1873; a member of the Medical Society of the State of New York; consulting physician to the German, Eastern District and St. Catharine's Hospitals, Brooklyn; died at his home, June 30, from heart disease, aged 65.

George Glick, M.D. Eclectic Medical Institute, Cincinnati, Ohio, 1849; for many years president of the First National Bank, ex-postmaster, member of the city council and school board of Marshalltown, Iowa; died at the home of his daughter in Chicago, June 26, from paresis, aged 83.

Edward Jerome Page, M.D. Louisville (Ky.) Medical College, 1874; Jefferson Medical College, 1883; a member of the Oregon State Medical Association, and the Southern Oregon Medical Association; president of the Commercial Bank of Oakland; died at his home in that city, July 1, aged 60.

Alfred Willard Southgate, M.D. Harvard Medical School, Boston, 1905; a member of the Massachusetts Medical Society; a member of the staff, and for two years house surgeon of the City Hospital, Worcester; died in that institution, June 25, from tuberculosis, aged 31.

Charles B. Richmond, M.D. Northwestern University Medical School, Chicago, 1878; a member of the American Medical Association; for thirty years a resident of Colorado and twenty-one years a practitioner of Denver; died at his home in that city, July 1, aged 56.

Simon B. Beer, M.D. Eclectic Medical Institute, Cincinnati, Ohio, 1874; of Fairview, Ill.; served in the One Hundred and Third and Thirty-sixth Illinois Infantry throughout the Civil War; died in a hospital in Peoria, June 23, following an operation, aged 72.

James Robertson Ely, M.D. University of Louisville (Ky.) Medical Department, 1859; a member of the Kentucky State Medical Association; formerly of Frankfort, Ky.; died at the home of his son-in-law in Tryon, N. C., June 19, from sepsis, aged 74.

Daniel A. Sheffield, M.D. Northwestern University Medical School, Chicago, 1867; Rush Medical College, Chicago, 1886; formerly of Apple River, Ill.; died at the home of his daughter in Lamont, Iowa, June 25, aged about 80.

Joseph F. Koerper, M.D. Philadelphia College of Medicine and Surgery, 1852; a member of the Medical Society of the State of Pennsylvania; died at his home in Philadelphia, March 18, from senile debility, aged 79.

Joseph Hark, M.D. Franklin Medical College, Philadelphia, 1848; a retired practitioner of Bethlehem, Pa.; died at the home of his grandson in Bethlehem, June 18, from fatty degeneration of the heart, aged 91.

Addison Norvel Nuckols, M.D. Medical College of Virginia, Richmond, 1870; a Confederate veteran; a resident of Danville, Va., until two years ago; died at his home in Lynchburg, June 9, from apoplexy, aged 66.

Robert Edward Emmett Burke, M.D. University of Louisville (Ky.) Medical Department, 1905; formerly intern at the City Hospital, Louisville, Ky.; died at his home in that city, June 28, from tonsilitis, aged 26.

Edwin Drake Van Deventer, M.D. Missouri Medical College, St. Louis, 1881; a member of the Missouri State Medical Association; of Laddonia, Mo.; was struck and killed by a Chicago & Alton train, July 4, aged 51.

John Philip Harrell, M.D. Keokuk (Iowa) Medical College, 1892; a member of the Iowa State Medical Society; formerly city physician of Burlington, Iowa; died at Mercy Hospital in that city, June 28, aged 42.

William Lobdell Johnson, M.D. Albany (N. Y.) Medical College, 1865; a member of the Medical Society of the State of New York; died at his home in Johnstown, June 26, from chronic gastritis, aged 66.

Charles DeWitt Early, M.D. Rush Medical College, Chicago, 1901; formerly county physician at Peoria County, Illinois; died suddenly while seated in a chair at the Elks' Club, Peoria, July 5, aged 32.

Walter William Snyder, M.D. Starling Medical College, Columbus, Ohio, 1901; a member of the Ohio State Medical Association; was found dead at his home in London, Ohio, June 26, aged 34.

Clarence Roberts Campbell, M.D. College of Physicians and Surgeons, Baltimore, 1906; of New Bedford, Mass.; died at the home of his brother in Provincetown, Mass., June 19, from pneumonia.

Donald Alex. McDonald, M.D. University of Michigan, Department of Medicine and Surgery, 1876; of Detroit, Mich.; died in Rochester, Minn., May 29, from gastric ulcer, aged 50.

Charles L. Sonnemann, M.D. Northwestern University Medical School, Chicago, 1894; of Milwaukee, Wis.; died at the home of his brother-in-law, June 23, of nephritis, aged 41.

Richard Joseph Nunn, M.D. Savannah (Ga.) Medical College, 1854; a member of the Medical Association of Georgia; a Confederate veteran; died at Savannah, Ga., June 30, aged 79.

Frank B. Dodge, M.D. College of Physicians and Surgeons, Baltimore, 1880; a resident of Mount Morris, N. Y., for twenty-eight years; died at Fresno, Cal., June 22, aged 70.

Benjamin Franklin Daniel, M.D. Atlanta (Ga.) Medical College, 1887; formerly of Union Point, Ga.; died at his home in Decatur, Ga., June 27, from tuberculosis, aged 60.

John Waters Deshon, M.D. Bellevue Hospital Medical College, New York City, 1891; formerly of Little Rock, Ark.; died at Tulsa, Okla., July 3, from heart disease, aged 57.

John Whitehead Seidell, M.D. Atlanta (Ga.) College of Physicians and Surgeons, 1907; died at his home in Nichols, Fla., June 16, from typhoid fever, aged 28.

David Findley (license, Iowa, 1886); a practitioner of Cass County, Iowa, for forty-seven years; died at his home in Atlantic, June 28, from senility, aged 80.

Oliver H. Caldwell, M.D. Memphis (Tenn.) Hospital Medical College, 1882; a veteran of the Civil War; died at his home in West Paris, Texas, June 28, aged 78.

Thomas M. Young, M.D. Chicago Homeopathic Medical College, 1880; a veteran of the Civil War; died at his home in Seattle, Wash., July 1, aged 68.

John B. Heck, M.D. Louisville (Ky.) Medical College, 1874; formerly postmaster of Dayton, N. M.; died at his home in that place, recently, aged 60.

Sebastian Cabot Lewis, a resident of Kerens, Texas, for twenty-two years; died at that place, June 21, from senile debility, aged 91.

Samuel H. Decker (license, Pa., 1891); formerly of Benezett, Pa.; died at his home in Kersey, Pa., April 7, from pneumonia, aged about 65.

Elizabeth Short, M.D. Woman's Medical College, Kansas City, Mo., 1898; died at her home in Kansas City, July 1, aged 44.

Sylvanus F. Heath, M.D. Harvard Medical School, Boston, 1866; died at his home in Gilman, Ill.; June 16, aged 71.

Pharmacology

QUININ ARSENATE REFUSED RECOGNITION

Report of the Council on Pharmacy and Chemistry

The advisability of admitting quinin arsenate as a non-proprietary article to New and Nonofficial Remedies was taken up for consideration by the Council and the product was referred to a committee on chemistry. This committee recommended that the opinion of the staff of clinical consultants should be obtained relative to the value of this product. This was done and on the staff's recommendation the drug was refused recognition and the Council ordered the following statements to be published.

W. A. Puckner, Secretary.

Quinin arsenate is the secondary quinin salt of arsenic acid. It contains 8 per cent. of elementary arsenic and 69 per cent. of anhydrous quinin. 0.1 gm. (1½ grains) would be equivalent to approximately .092 gm. (1 9/20 grains) of quinin sulphate and to 0.032 gm. (½ grain) of sodium arsenate (five times the official dose). It is thus seen that the proportions of the two chief ingredients in the salt are such that an efficient dose of quinin cannot be given in this form without introducing a dangerous amount of arsenic. As it does not appear that this preparation possesses any properties that might not be found in a mixture of quinin salts and various preparations of arsenic, and as it has no advantage over other forms of arsenic now available there is no reason for including it among unofficial non-proprietary remedies. Attempts to substitute it for other quinin salts would be likely to lead to overdosing with arsenic.

THE DEADLY HEADACHE POWDER

Two Widely Advertised Nostrums Add to Their Mortuary Lists

Yet another death is recorded from the use of the deadly "headache powder." According to the reports, Mrs. Lena Shepland, Hastings, Neb., having a headache, took a dose of bromo-seltzer; this not giving the desired relief, she also took a dose of antikamnia. An hour later she was dead from heart failure induced by these heart-depressing nostrums.

The *Hastings Daily Tribune* in reporting this case demonstrates the change that the daily press has undergone in the past five years. Not only do the names of the nostrums appear in the report but also in large type in the heading. This seems to show that the Proprietary Association of America is losing its grip on the press. Five years ago it would have been hard to find a paper that would have dared to give a nostrum such unenviable notoriety as this Nebraska paper forces on bromo-seltzer and antikamnia.

RADAM'S MICROBE KILLER

A correspondent asks for information concerning "Radam's Microbe Killer," as he has a patient with cancer whose family are strongly urging the use of this nostrum.

"Radam's Microbe Killer" was shown up by Mr. Adams in his "Great American Fraud" series and also in the report of the Australia Royal Commission. This nostrum had a great vogue some years ago and then seemed to drop out of notice; apparently, however, it has been revived recently and is being pushed vigorously, especially in New York City and on the Pacific coast. A few months ago the federal government seized a consignment of this preparation (see The Journal, May 14, 1910) and served notice on the firm in whose possession it was found. The court decided that the product should be destroyed and that the firm in question shall pay all the costs of the proceedings. The "Notice of Judgment" published by the government did not give in detail the results of the government analysis, but application to the Department of Agriculture regarding the composition of this nostrum brought the following letter:

"The acting secretary has officially authorized giving you the information relative to the composition of 'Radam's Microbe Killer.' The results are as follows:

"Sulphuric acid	0.59 per cent.
"Sulphurous acid	0.016 per cent.
"Inorganic matter (ash)	0.013 per cent.
"Water by difference	99.381 per cent.

"The above clearly shows that 'Radam's Microbe Killer' is a mixture of sulphuric acid and sulphurous acid dissolved in ordinary hydrant water. It is quite possible that the sulphuric acid may have been present in part as sulphurous acid."

A REDISCOVERY

Fifteen years ago The Journal ceased to carry the advertisement of antikamnia; ten years ago it called attention to the fact that this nostrum was being advertised to the laity by means of circular letters; since that time it has persistently exposed the devious ways in which the exploiters of this dangerous powder have humbugged the medical profession and the public. Some other medical journals, notably the *Medical World*, have enlightened their readers on the same subject. It can hardly be said, therefore, that the medical profession was unaware of the "heads I win, tails you lose" policy of the Antikamnia Chemical Company.

Apparently, however, our friends the druggists, were unaware of the machinations of the Antikamnia people. This, at least, is what we are led to believe by a letter which has recently been sent to physicians by the committee on the U. S. P. and N. F. propaganda of the Chicago branch of the National Association of Retail Druggists. With its own letters calling attention to the way in which physicians have been made the catspaw of the proprietary interests, this committee sends a facsimile letter of the "Do-you-suffer-pain?" letter which the Antikamnia people have been scattering among the laity for years.

This change in attitude on the part of the N. A. R. D. is encouraging. It is less than five years ago that the Antikamnia Chemical Company sent "as a Thanksgiving Offering to the National Association of Retail Druggists, our check for the sum of five hundred ($500.00) dollars." This money the N. A. R. D. gratefully received and acknowledged with the statement that the Antikamnia Company deserved great credit for realizing "that the retail druggist is, after all, the best friend of the proprietary manufacturer." And at the time this "honorarium" was accepted by the N. A. R. D. these same "Do-you-ever-suffer-pain?" letters had been going to the public for over five years. Reforms come slowly, however, and it is sufficient to be thankful for them when they arrive. The medical profession should appreciate the present attitude of the N. A. R. D. toward at least one of the "ethical" nostrums even though that attitude is brought to their attention in the form of a discovery at least a decade old.

Correspondence

Treatment of Burns; Correction of a Prescription

To the Editor:—In my paper on "Rational Treatment of Burns" (The Journal A. M. A., July 2, p. 27), an error [Our error.—Ed.] exists in regard to the strength of the picric acid solution. The prescription as used by me and given in my manuscripts is as follows:

	gm. or c.c.	
Picric acid	4	ʒj
Alcohol	64	℥ ji
Water q. s.	768	O jss

Please make this correction in The Journal, as serious results might follow the use of a picric acid solution as strong as the one erroneously printed in my paper of the above date.

H. L. Fancher, M.D., Chattanooga, Tenn.

Bismuth Subnitrate Superior to Bismuth Milks

To the Editor:—There are a number of bismuth preparations on the market put out by manufacturing chemists in the shape of *bismuth creams, milks, etc.*, purporting to have the same field of usefulness in gastrointestinal disorders as bismuth subnitrate. I believe these preparations are made from the oxid and while, from a pharmaceutical standpoint, they seem to leave nothing to be desired, clinically, I am convinced, they are well nigh worthless, at least in infants.

In a series of observations covering their administration to twenty-one infants suffering from acute gastroenteric conditions, I failed to observe a sedative or astringent action in a single case. In 21 cases I gave four ounces of a well-known bismuth milk in thirty-six hours to infants suffering from gastroenteritis, with frequent stools containing some blood and abundant mucus, without the slightest appreciable effect in the character or frequency of the stools notwithstanding the fact that milk feeding was entirely withheld during this treatment for a period of seven days. The bismuth milk passed through the entire alimentary tract practically unchanged and appeared in the stools as a white semi-solid mass. Bismuth subnitrate was now administered in 10 gr. doses every two hours resulting in darkened stools, lessened amount of blood and almost complete disappearance of mucus within the first twenty-four hours of its administration.

Judson A. Hulse, M.D., Akron, Ohio.

The Public Service

Medical Department, U. S. Army

Changes for the week ended July 9, 1910:

Slater, E. F., M. R. C., granted 12 days' leave of absence about Aug. 15, 1910.

Fisk, Owen C., M. R. C., ordered from Fort Crook to Fort Omaha, Neb., for temporary duty.

Roberts, William M., major, left Fort Thomas, Ky., en route to Camp at Gettysburg, Pa.

Gosman, George H. R., major, reported for duty at Chickamauga Park, Ga.

Smith, Allen M., major, left Washington, D. C., *on 30 days' leave* of absence.

Hammond, William G., dental surgeon, relieved from duty in the Philippines Division and directed to sail on transport to sail from Manila, P. I., about *Sept. 15, 1910, to San Francisco.* Dental Surgeon Hammond will proceed thence to his home and on expiration of the leave of absence granted him this date will report to the Surgeon General of the Army for annulment of contract. Leave *of absence for 3 months, to take effect* on arrival in the United States, is granted.

Mills, Frederick H., M. R. C., granted 4 months' leave of absence about Sept. 15, 1910.

Gray, William W., col., leave of absence extended 1 month.

Harris, Herbert I., M. R. C., granted leave of absence for 1 month and 15 days.

Register, Edward C., M. R. C., assigned to permanent duty at Fort H. G. Wright, N. Y.

Adams, Paul A., M. R. C., died at Scofield Barracks, H. Ty., July 3, 1910.

Baker, David, major; Darby, Taylor E., lieut.; Northington, E. G., M. R. C., report arrival at Chickamauga Park, Ga.

Kramer, Floyd, lieut., left Fort Robinson, Neb., en route to Fort D. A. Russell Target and Maneuver Reservation, Wyo., for duty.

Brown, Henry L., capt., reported for duty at Chickamauga Park, Ga.

Griswold, W. C.; Meterick, R. H., M. R. C., left Fort Oglethorpe, Ga., en route to Camp of Instruction, Chickamauga Park, Ga.

Gunckel, George I., dental surgeon, en route to Fort McPherson, Ga., from temporary duty at Fort Screven, Ga.

Mount, J. R., lieut., *reported for duty* at Camp Dickinson, Chicago.

Brooks, William H., major, ordered to Columbus Barracks, Ohio, *for temporary duty. Major Brooks to be relieved from duty at* Presidio, San Francisco on completion of *temporary duty* at Columbus Barracks, Ohio, and will then proceed to Recruit Depot, Fort McDowell, Cal., for duty, relieving Lieutenant Colonel Euclid B. Frick, Medical Corps.

Frick, Euclid B., lieut. col., on being relieved from duty at Fort McDowell, Cal., will proceed to and take station at the Presidio of San Francisco.

Medical Corps, U. S. Navy

Changes for the week ended July 2, 1910:

Sellers, F. E., P. A. surgeon, detached from duty at the Naval Station and Naval Recruiting Station, New Orleans, and *ordered* to the Naval Station, Guam, M. I.

Dunn, H. A., P. A. surgeon, ordered to duty at the Naval Medical School Hospital, Washington, D. C.

Stepp, J., P. A. surgeon, ordered to the *Wabash*.

Wheeler, L. H., P. A. surgeon, detached from the *Marietta* and ordered to the *Virginia*.

Stritel, C. E., P. A. surgeon, discharged from treatment at the Naval Hospital, Las Animas, Colo., and ordered *to Washington*, D. C., for examination for retirement and thence home to wait orders.

Philips, E. W., asst.-surgeon, detached from the Naval Hospital, New York, and ordered to the *Marietta*.

Hoyt, R. E., P. A. surgeon, ordered *to the* Naval Recruiting Station, Buffalo.

Garrison, H. A., asst.-surgeon, detached from the Naval Station, Guam, M. I., and ordered home to wait orders.

Tolfree, H. M., P. A. surgeon, ordered to the Naval Recruiting Station, Cleveland, Ohio.

White, E. C., P. A. surgeon, detached from the Naval Hospital, Newport, R. I., and ordered to the Naval Recruiting Station, St. Louis.

Payne, J. H., P. A. surgeon, having completed examination for promotion, ordered home to wait orders.

Jacoby, A. L., acting asst.-surgeon, ordered to duty at the Naval Hospital, Newport, R. I.

Rennie, W. H., P. A. surgeon, detached from the Naval Recruiting Station, St. Louis; ordered home and granted sick leave for 3 months.

Duhigg, J. T., asst.-surgeon, ordered to the Naval Recruiting Station, Cincinnati.

Baker, M. C., asst.-surgeon, detached from the Naval Recruiting Station, Cincinnati, and ordered to the Naval Training Station, Newport, R. I.

Woodland, E. E., acting asst.-surgeon, ordered to duty at the Naval Hospital, Philadelphia.

U. S. Public Health and Marine-Hospital Service

Changes for the week ended July 6, 1910:

Kerr, J. W., asst.-surgeon general, granted 1 month's leave of absence from July 7, 1910.

Long, J. D., asst.-surgeon general, directed to proceed to Columbus, Ga., on special temporary duty.

McIntosh, W. P., surgeon, granted 4 days' leave of absence from July 5, 1910.

Nydegger, J. A., surgeon, granted 7 days' leave of absence from July 3, 1910.

Grubbs, S. B., P. A. surgeon, granted 4 days' leave of absence en route to station.

Lumsden, L. L., P. A. surgeon, directed to proceed to Norfolk, Va., on special temporary duty.

Anderson, John F., P. A. surgeon, granted 5 day's leave of absence from July 5, 1910. Paragraph 189, Service Regulations.

Leake, J. P., asst.-surgeon, granted 7 days' leave of absence from June 24, 1910. Paragraph 191, Service Regulations.

Altree, G. H., acting asst.-surgeon, granted 30 days' extension of leave of absence from May 3, 1910, on account of sickness.

Duffy, Francis, acting asst.-surgeon, granted 4 days' leave of absence from July 6, 1910.

Houghton, M. W., acting asst.-surgeon, granted 2 days' leave of absence from July 2, 1910.

Morgan, Roy, acting asst.-surgeon, granted 7 days' leave of absence in June, 1910. Paragraph 210, Service Regulations

Stewart, W. J. S., acting asst.-surgeon, granted 1 month's leave of absence, without pay, from June 23, 1910.

Story, Henry C., acting asst.-surgeon, granted 30 days' leave of absence from July 1, 1910.

Walker, T. D., acting asst.-surgeon, granted 11 days' leave of absence from June 28, 1910.

Wetmore, W. O., acting asst.-surgeon, granted 5 days' leave of absence from June 8, 1910, and 1 day's leave June 15, 1910, under paragraph 210, Service Regulations.

Queries and Minor Notes

Anonymous Communications will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

HOSPITALS FOR CANCER PATIENTS

To the Editor:—Does the Rockefeller Institute or Hospital for the treatment of cancer receive patients at present? Are there any similar hospitals elsewhere in the country? I have a patient with a cancer in the primary stage whose case would be suitable for such a hospital. T. W. Longfellow, Windfall, Ind.

Answer.—As we understand it the Rockefeller Hospital, now nearing completion, adjoining the Rockefeller Institute, is not to be especially a cancer hospital, but is intended to cover the whole field of medical research. The hospital will not be open for some weeks. When it is opened it will be used to care for a limited number of patients, preferably those suffering from the heretofore incurable diseases; the work will be largely experimental, and the patients received there will have consented to a participation in this experimental work. The Skin and Cancer Hospital in New York City and the Skin and Cancer Hospital in St. Louis are both excellent institutions.

Medical Economics

THIS DEPARTMENT EMBODIES THE SUBJECTS OF ORGANIZATION, POSTGRADUATE WORK, CONTRACT PRACTICE, INSURANCE FEES, LEGISLATION, ETC.

COUNTY SECRETARIES MEET IN WISCONSIN

The first annual meeting of the Association of County Secretaries and State Officers of Wisconsin was held in Milwaukee, June 21, 1910. Dr. C. S. Sheldon of Madison stated that the object of the organization was to enable county secretaries to get together, to meet with the state secretary and with each other, and to talk over the methods and most successful manner of conducting county society work. Officers were elected as follows: Dr. T. J. Redelings, Marinette, president; Dr. Rock Sleyster, Waupun, secretary; Dr. W. F. Zierath, Sheboygan, vice-president.

Dr. C. S. Sheldon presented a paper on the aims and designs of this association, in which he disclaimed originality as to the idea of such an organization. Accounts of similar organizations in other states had greatly impressed him with their usefulness in bringing the county secretaries into closer touch with the work of the state society and with each other. He told of the services of Dr. Sleyster and of his scheme of the "Booster Club" and the "2,000 for Milwaukee in 1910," and said that Dr. Sleyster had clearly vindicated his title of "Head Booster" and that the outcome of the present meeting would determine the measure of his success. He reviewed the results of organization thus far accomplished in the endeavor to transform the 150,000 disorganized doctors into one compact and harmonious body, and said further: There has been too much jealousy in the profession, resulting in the lowering of the public estimate of the whole profession. The medical expert has become discredited, and malpractice suits are made easy by the alliance of disloyal medical men with unprincipled shysters. The effort to secure sorely needed legislation has been ineffective. Medical men are not accorded the respect and consideration which they deserve, as shown by the ready acceptance of such fads as Eddyism, osteopathy and the like. The solution of these problems has been undertaken by the American Medical Association. The county medical society is the unit of organization and membership therein is the condition of membership in the district, state or national organizations. Organization is proving effective though much is still to be accomplished. Since the movement began the standards of medical education have been advanced and the work of the colleges improved, medical legislation has gone steadily forward, and sanitation and preventive medicine have made great strides.

Time has vindicated the adoption in Wisconsin of the reorganization plan. Previous to its adoption, in spite of the most strenuous and persistent effort, not over a dozen county societies could be kept alive, while the state medical society numbered only about 600, whereas now there are 54 regularly organized county medical societies and a membership in the state medical society of over 1,500. The present meeting was called to discuss conditions in the state and to endeavor to increase the efficiency of the society at least 25 per cent. during the coming year.

A grave responsibility rests on the county secretary, in securing and fostering the scientific spirit in the society, collecting dues, maintaining the organization, securing the best possible programs for meetings, and bringing the members into pleasant social relations. The object and aim of the association is to discuss ways and means to bring about these results and to keep the organization alive and vigorous.

Dr. Sleyster presented a paper on "Some Things This Association Can Accomplish." He said that what could be accomplished might be summed up in these words: It is a chance to get together and talk things over; to learn what your neighbor is doing and how. New ideas and methods are brought to the notice of each member, and adopted by him. Of even more importance is the inspiration and enthusiasm the county secretary should take home with him from a meeting of this kind. He will learn the ideals and results accomplished elsewhere, and obtain a fuller realization of the possibilities of his position. What has been accomplished in national, state or county organizations can be accomplished at home. The standing of the profession with the public is largely dependent on local organizations.

Dr. Sleyster suggested the giving of an hour's time in each society at an early meeting in the year to discussing the nonmembers in the county, and the appointment of a committee to get applications from these non-members; the appointment of a special membership committee to work for new members and the inviting of eligible non-members to each meeting. He urged the holding of a "Booster Meeting" each year, and to begin the campaign early, make careful and accurate plans, and then carry them out. He emphasized the value received for the membership fee paid, showing that each member received the state journal, membership in both county and state societies and malpractice insurance. He advocated the passage of a resolution in each organization instructing the secretary to make a sight draft on a specified date on each member in arrears and thus relieve the secretary of the trouble in connection with collections; that reports of each meeting be sent to the journal; that members be optimistic in writing or speaking of their society; and that formal dignity be dropped when meeting as doctors and friends; and last, and above all else, that each member "be a booster."

Dr. George H. Simmons of Chicago delivered a short address in which he congratulated the association on the good sense of the arguments, suggestions and helpful thoughts contained in the papers which had been presented. He reviewed the plan of improved organization adopted by the American Medical Association by which the county society was made the unit of representation in the state societies and in the American Medical Association. The fundamental thing is the county society, the door through which one must enter to become a member of the state society or of the American Medical Association. The county society elects the members of the state house of delegates, who in turn elect the delegates to the American Medical Association.

Hence the county society should take more interest in what the American Medical Association and the state societies are doing and should be prepared to approve or disapprove. They should devote one meeting each year to the discussion of national and state problems and should instruct their delegates to the state society what position to take on the various questions under discussion and in like manner the delegates to the American Medical Association should represent the views of the majority. Formerly the state society did not appreciate the enormous importance of the House of Delegates of the American Medical Association, but now it has begun to realize the importance of picking representative men as delegates.

At present there are two especially important things before the association, one being the work in connection with medical education, in which every physician should take great interest, and the other the work of the Council on Pharmacy and Chemistry, which should appeal to every physician. If this work is in accordance with the views of the members, it should be so expressed in the county society where the matters should be discussed.

Dr. Simmons called attention to the *Bulletin of the American Medical Association*, published to enlighten the men in charge in the state societies—the councilors, county secretaries and presidents of county societies—containing accounts of the subjects under consideration, i. e., medical education, medical legislation, etc., and to the importance of those subjects, and suggested bringing the *Bulletin* to the county society meeting and discussing the subjects. The American Medical Association and its committees want the views of the individual members as to whether the work being done is in accord with their opinions. We have the machinery, he said, but we have not yet begun to work with the machinery. He emphasized the necessity of securing a good live secretary for the county society. He said that one of the best movements yet started in connection with this work was the organization of these associations of county secretaries, and that provision ought to be made whereby the county secretary should be able to attend these meetings and his expenses be paid. It would do more to help bring about better conditions than any other one thing; and bettering conditions means putting the medical profession higher in the estimation of the people.

Dr. G. Windesheim of Kenosha spoke on "The Relation of the Councilor to the County Society." He called attention to the fact that under the reorganization plan, the councilor was able to be of little benefit to the county society. He is no more the peacemaker, organizer and censor for the county societies but is simply the go-between of the county society and the state society. Each county society should hold a special meeting each year, at which the councilor of the district is present, and discuss such matters as refer to the state society and to the American Medical Association, with which the councilor is supposed to be familiar, and thus explain such matters as may be perhaps misunderstood, and so save the membership of a few men to the state society.

It is questionable whether the office of councilor is really necessary at the present time, except as trustee of the state society, unless some such plan can be adopted. At these meetings the delegates to the next state society meeting should be present and should be instructed as to the question to be brought before the House of Delegates. In that way the state society would get an idea as to what the county societies and the profession generally want.

Dr. H. W. Abraham of Appleton presented a paper on "The Year's Program of the County Society; How Can We Promote Greater Scientific Interests?" in which he said: The scientific program of a medical society is not the most important function of that body. Perfect organization, which includes the best of good fellowship, is the primal object. To be successful, both scientifically and financially, it is necessary to systematize and organize after the manner of a great business enterprise. The scientific program should be the postgraduate school of the profession. Every man should have some favorite line of study each year and should give the results of his studies—clinical experiences, study and review of the literature along some particular line, or original investigation. The program should be the subject of considerable inquiry on the part of the committee. Hunt out a number of individuals having a special interest in some particular subject; give them plenty of time to prepare. As a general rule, a paper should not take up a subject in the order of a text-book. It would stimulate interest and discussion if papers were so written as to emphasize the advances made, by comparison of old with new methods. Each year's program might have a paper on the newer methods of diagnosis brought out during the year; another on advances in therapeutics; another on new surgical methods, and so forth. The progress made each year in medical chemistry and physiology should be brought before the society. Many do not take medical periodicals, and would be more interested in the scientific aspects of medicine by thorough discussion. Cases in which a post-mortem examination has shown a mistake in diagnosis should be carefully written up, bringing out the clinical symptoms and signs that lead to the diagnosis, as such papers furnish a rich field for discussion and are of great practical value. Questions of medical ethics should be brought before the members for discussion. A paper should be read at least once a year on the work done by the American Medical Association. Personal work on the part of officers, especially the secretary, as to the obligation to do good work, which rests on those presenting papers, would be of value.

To sum up, a program is interesting: 1. When the papers are brief. 2. When they stimulate discussion. 3. When they arouse interest for further reading. 4. When they give the results of original work. 5. When stating clearly the advances made in medical science. 6. When they show originality in arrangement and composition.

Dr. M. V. DeWire of Sharon presented a paper on "The Business Side of the Secretary's Work." He said: In the majority of instances the work of the county secretary includes the management of the whole society; keeping the records; collecting dues; remitting to the state society; incurring expenses and paying bills; arranging for time and place of meeting; working up the program; looking after social features; arranging for the clinical cases; printing and mailing programs; soliciting new members and keeping the machinery of the society well oiled and in good running order. The number of meetings each year will vary with the number of members, their convenience in getting together and transportation facilities. The arrangement of the program will depend largely on the turn of mind of the majority of the members and as to whether they are surgeons, obstetricians, internists, etc. It is well to alternate the subjects, and it is advantageous to make here a symposium on the subject so as to be able to discuss it from all angles. The programs should not be too long, but should give ample time for discussion. Social features are an advantage. It is best to arrange a program for at least three months in advance. Clinical cases are a great help and serve to make a deeper impression of the points brought out. Members should be urged to bring such cases before the meeting, and patients can often be persuaded to come by explaining that they will get the benefit of the experience of the entire society. Invitations should be printed and mailed at least a week before the meeting.

As to little infractions of the "Principles of Ethics," patience and ingenuity on the part of the secretary are required. In nine cases out of ten, by seeing the member and talking to him you can usually show him his mistake, and he will be grateful to you for calling his attention to it. Use all the tact you have, all you can borrow and then use more tact.

Dr. J. H. Cleary of Kenosha presented a paper on "Social Features of the County Society." He said: Man is preeminently a social animal, and doctors are no exception. The mere gathering together in a society constitutes a social feature of no mean standing and proves the prime importance of the social element in all human organizations. In order to hold the continued interest of a body of men it is necessary to contribute to their mental or material welfare or to amuse them and most frequently both are necessary. A doctor's life being a serious one, anything that takes his mind from his daily work and furnishes relaxation assumes greater importance in medical organizations than in most other societies. Under the new era of systematic organization in medicine the need for social features in basic societies becomes more apparent. Bickering and enmity cannot long endure the mellow sunshine of the social hour. We must consider the opportunities for social features. In our county we find that holding meetings at the homes of members by invitation guarantees successful meetings, with only sufficient formality to conduct the business of the society. The spirit of sociability and good fellowship prevails. Special amusements provided will depend on circumstances and available talent and varies in different communities. During the summer months one or two meetings may be held in the country, and in counties having inland lakes they should be utilized to the fullest extent. Why not make these summer diversions old-fashioned picnics and bring the ladies? Only too frequently differences are carried into the families of physicians, and the presence of the families would contribute to the desired harmony and a better acquaintance. The annual meeting should be a feature of the county society, and should be made a special occasion. The business being completed in a short time, the social features can be elaborated, and may consist of a banquet and accompanying features. Special meetings may be provided or a regular meeting may be utilized in which to collaborate with neighboring counties. We have had some experience with these joint meetings in Kenosha and they were very enjoyable affairs. The social features of the county society should be in charge of a special committee, and not left to the overworked county secretary.

State Boards of Registration

COMING EXAMINATIONS

ILLINOIS: Coliseum, Chicago, July 20-22. Sec., Dr. James A. Egan, Springfield.

MAINE: Augusta, July 19-20. Sec., Dr. F. W. Searle, Portland.

OHIO: Cincinnati, July 19-21. Sec., Dr. Geo. H. Watson, Columbus.

Minnesota April Report

Dr. W. S. Fullerton, secretary of the Minnesota State Board of Medical Examiners, reports the examination held at St. Paul, April 5-8, 1910. Aside from the written examination, practical tests were given in anatomy, pathology, histology, bacteriology and urinalysis. The number of subjects examined in was 10; total number of questions asked, 100; percentage required to pass, 75. The total number of candidates examined was 18, of whom 16 passed and 2 failed. Ten reciprocal licenses were granted at this examination. The following colleges were represented:

PASSED

College	Year Grad.	Per Cent.
Rush Medical College	(1910)	88.3
Northwestern University Medical School	(1909)	77.9
College of Physicians and Surgeons, Chicago	(1905)	85.4
Johns Hopkins University	(1908)	90.1
University of Maryland	(1909)	91.2

California April Report

Dr. Charles L. Tisdale, secretary of the California State Board of Medical Examiners, reports the written examination held at San Francisco, April 5-8, 1910. The number of subjects examined in was 10; total number of questions asked, 100; percentage required to pass, 75. The total number of candidates examined was 90, of whom 73 passed, including 13 osteopaths, and 17 failed, including 3 osteopaths. The following colleges were represented:

* Fell below 60 per cent. in one or more branches.

The following questions were asked:

ANATOMY

1. Trace cerebrospinal fluid from the lateral ventricles to the spinal canal. 2. Describe the ramicommunicantes. 3. Name the bones of the tarsus. Use diagram. 4. Indicate, on the diagram, the points of exit from the pelvis of the following nerves: External cutaneous, anterior crural, genitocrural, obturator, sciatic, pudic, superior gluteal. 5. Indicate, on the diagram, the course of the

common, internal and external iliac arteries. 6. What veins are without valves? 7. What cranial nerves are distributed to muscles only, i. e., are motor? 8. Give topographic outline of the lungs and bronchi on the anterior chest wall. Use the diagram. 9. Give origin and course of the eleventh cranial nerve as far as its exit from the skull. 10. What are the characteristics of arthrodial joints? Give five examples of this class of joints. 11. What is the ischiorectal fossa, how bounded and what does it contain? 12. When the arm is hanging with palm forward, what bony prominences at shoulder, elbow and wrist are normally in line?

HISTOLOGY

1. (a) Name the structures found in red bone marrow; (b) give the function of red bone marrow. 2. Draw diagram illustrating lung tissue, naming different structures. 3. Explain the difference between the mucosa of the endometrium and that of the vaginal portion of the cervix. Also make drawing. 4. Give structure of the tonsil. 5. From which germ layers are the following derived: Pancreas, spleen, large intestine, salivary glands, fat? 6. Draw a transverse section of the brain, at a point just anterior to the pons varolii. Name most important parts. 7. Draw diagram illustrating a cell and name all the necessary constituents. 8. Describe the structure of the liver. 9. Explain the difference between the white and gray matter of the brain. 10. What are terminal arteries? Name organs which are so supplied. 11. Identify slides. 12. Identify slides.

BACTERIOLOGY

1. What are the differences in structure, methods of multiplication sporulation, etc., between the blasmycetes or yeasts and bacteria? 2. What changes are produced on the culture media when *Bacillus coli communis* is grown: (a) on gelatine, (b) in milk, (c) in dextrose, (d) in lactose. 3. Describe the conditions necessary to successfully grow *Bacillus tetani* and the appearance of a stab culture in agar or gelatin about the sixth day. 4. What is the difference between an antitoxin and a bacterial vaccine? 5. Name four pathogenic anaerobic bacteria. 6. Differentiate between the bacillus of tuberculosis and *Bacillus lepræ* taking into consideration staining, culture peculiarities, effect on tissues and relation to tissue cells of the host. 7. Describe briefly how you would make gelatin plate cultures, using material from a furuncle as the source from which to obtain the germ. 8. Name ten pathogenic bacteria that are Gram-positive. 9. What do you understand by the opsonic index? 10. How would you sterilize (a) a culture tube of gelatin, (b) a glass container with rubber stopper, (c) a platinum needle in a glass handle. 11. Identification of cultures. 12. Identification of slides.

CHEMISTRY

1. What is the poison in most headache powders? Its effect? Antidote? 2. Mention six elementary substances commonly used in their pure state in medicine. 3. What does the presence of an abnormal quantity of chlorin in drinking water indicate? 4. How would you detect the presence of bile in the urine? Give two tests. 5. Give the reaction, specific gravity and percentage of fats in normal cow's and woman's milk. 6. Mention a secretion in the body that contains cholesterin, one that contains pepsin, and one that contains trypsin. 7. What antidotes should be used in phosphorus poisoning? Explain the action of each. 8. Define and illustrate (a) capillary attraction, (b) absorption, (c) diffusion, (d) osmosis, (e) endosmosis. 9. In what principal form is nitrogen eliminated from the body? Give the chemical properties of nitrogen. 10. What is the chemical composition of the various renal calculi? 11. Mention one chemical antidote for each of the following: (a) Phenol, (b) arsenious oxid, (c) sulphuric acid, (d) mercuric chlorid, (e) oxalic acid. 12. What are the distinguishing characteristics of urates and uric acid as found in the urine? Give test for uric acid.

PHYSIOLOGY

1. How and where is lymph formed? 2. Discuss sleep and its causation. 3. Discuss briefly the influence of the nervous system on the digestive secretions. 4. Describe the movements of the intestines during digestion. 5. (a) Explain the eff[illegible] expiration on the volume of the brain. (b) Inspiration. 6. D[illegible] function and fate of glycogen. 7. What is the [illegible] between the brain of man and that of lower animals? 8. Under what circumstances may functional union be made between fibers of different nerve trunks? What practical value has this operation? 9. Give nerve supply and action of muscles concerned in the movements of the eyeball. 10. Do we determine the function of a nerve by the location or function of the center from which it comes or by its peripheral connections? Give your reasons. 11. What is the effect of a destructive lesion in the posterior limb of the internal capsule? 12. To what extent is the secretion of sweat under nervous control? Vascular?

PATHOLOGY

1. Describe the difference in the pathologic changes which take place in degeneration of the tissues and those which take place in atrophy. 2. Give the pathology of tabes dorsalis. 3. Describe the gross and microscopic changes which take place in the spleen, liver and kidneys as a result of prolonged exposure to malarial infection. 4. What are the postmortem changes usually found in diabetes mellitus in (a) children; (b) in adults of middle age; (c) in adults of advanced age? 5. What is the [illegible] blood pressure in adults from 50 to 60 years of age measure[illegible] f mercury? And describe the results if this pressu[illegible] a considerable time. 6. In bony tissue, what variety of malignant growths usually occur and why? 7. Under what conditions is cerebral embolism most likely to occur? What blood-vessels are most likely to be affected and why? 8. Describe the local lesion caused by infection by anthrax bacilli; the general or systemic effects and state how infection usually occurs. 9. Describe the condition present in acute dilatation of the heart. Give the immediate and predisposing causes and the usual final result. 10. State fully why urinary bladder disorders are so frequent and so resistant to treatment in both elderly men and in elderly women. 11. Identify 2 slides. 12. Identify 2 slides.

HYGIENE

1. Describe in detail the method of transmission of yellow fever. 2. What measures would you adopt to prevent the spread of typhoid fever during an epidemic? 3. What is a septic tank? Describe construction and explain how it acts. 4. What sanitary measures should be adopted in caring for tuberculous patients? 5. Name five of the most common intestinal parasites, and give a short description of each. 6. Give three ways of fumigating a room with formalin; also two methods with other disinfectants. 7. What effect have venereal diseases on the propagation of the human species? Explain. 8. How does the hookworm usually enter the human body? What means would you adopt to prevent its spread? 9. Describe the technic of vaccination and give the course of a successful case. 10. What is the period of incubation of the following diseases: Plague, smallpox, diphtheria, scarlatina, measles? 11. What is the object of placing traps on all waste pipes? What danger to health would arise if there were no traps? 12. Describe two types of water filter. What should be accomplished by a good filter?

OBSTETRICS

1. What zymotic diseases are liable to affect the pregnant and puerperal woman, and how? 2. How soon after the completion of the second stage of labor should the umbilical cord be ligated? How dressed? What are the dangers of improper dressing? 3. What injuries are liable to occur to the birth canal during labor? 4. Under what circumstances are anesthetics indicated in labor? What are the dangers? 5. What are the causes of premature rupture of the membranes? How does it influence the progress of labor? 6. How would you determine if a child is premature at birth? 7. Differentiate between retained and adherent placenta: the management of each. 8. What can be determined by external palpation of the pregnant woman at the eighth month? How should it be performed? 9. What are the so-called false pains of labor? Differentiate from true pains. 10. Rupture of the uterus, etiology and symptoms. 11. Give the physiology of menstruation, of ovulation, relation if any. 12. What is inversion of the uterus? Diagnosis and management.

GYNECOLOGY

1. Give the conditions justifying operative measures in fixed retro-displacement of the uterus. 2. Describe a pelvic hematocele and give the usual cause. 3. What is the pathology of pelvic cellulitis and what are the physical signs? 4. Name the most important causes of sterility. 5. Differentiate between a pudendal hernia and a pudendal hematocele. 6. What do you understand by the operation for perineorrhaphy? 7. Give the etiology and pathology of chronic endocervicitis. 8. Describe a case of carcinoma uteri and give some of the most prominent physical signs. 9. Discuss the matter of relative prognosis of cancer of the body of the uterus and cancer of the cervix. 10. Describe the mode of use and purpose of a vaginal tampon. 11. Differentiate between herpes of the vulva and chancre. 12. Name the muscles of the perineum and give the functions of the perineal body.

GENERAL DIAGNOSIS

1. Give the physical signs of a pleurisy with effusion. 2. Give the symptoms of bubonic plague. 3. Give the symptoms and physical signs of aortic insufficiency in the stage of failing compensation. 4. Give varieties, etiology and symptoms of chorea. 5. Give the symptoms of tabes dorsalis. 6. Describe a Colles' fracture. 7. Give the points on which you would make a diagnosis of cancer of the stomach. 8. Describe diabetes mellitus and differentiate it from diabetes insipidus. 9. Differentiate rubeola from scarlet fever. 10. Describe the secondary lesions of syphilis. 11. Give the symptoms of a transverse myelitis. 12. Give the symptoms of cholelithiasis.

Book Notices

THE ELEMENTS OF THE SCIENCE OF NUTRITION. By Graham Lusk, Ph.D., Professor of [illegible] Cornell University Medical College, New York City. [illegible] Cloth. Price, $3 net. Pp. 402, with 13 illustrat[illegible]: W. B. Saunders Co., 1909.

This is an important publication and deserves more than passing notice. Not only does this bring the whole subject up to date, but several of the chapters are practically rewritten, so great has been the advance in knowledge since the appearance of the first edition three years ago.

In the introductory chapter the author reviews the progress in our knowledge of nutrition, beginning with the "Aphorisms" of Sanctorius and following with a rather detailed account of the work of Lavoisier, Liebig, von Voit, Pettenkoffer, Pflüger, Rubner, and many others less widely known. Some fundamentally important truths of nutrition may well be quoted in the author's concise terms: "Metabolism in the body is not proportional to the combustibility of the substance outside the body; but protein, which burns with difficulty outside, metabolizes with the greatest ease; then carbohydrates; while fat, which readily burns outside, is the most difficultly combustible in the organism" (Voit).

"The quantity of oxygen needed in metabolism depends on the kind of material that burns in the organism. . . . The absorption of oxygen does not cause metabolism, but rather the amount of metabolism determines the amount of oxygen to be absorbed. The metabolism of the tissues, through its oxygen requirement and its carbon dioxid production, changes the condition of the blood and thereby regulates respiration."

An intelligent basis for the understanding of the process of nutrition is best acquired by a study of the organism when it is living at the expense of materials stored within itself, as it does in starvation. In the chapter on starvation is explained that during starvation an animal lives on its fat and protein and that its length of life depends on these. When there is no fat, protein may burn exclusively, therefore "the quantity of the protein metabolism in starvation depends on the amount of fat in the body." "The actual loss of body weight is greater when protein is the source of energy than when the energy is derived from fat," because it requires 33 gm. of protein to yield 26.4 calories of heat, while 2.8 gm. of fat will yield the same.

The chapter on the regulation of temperature is a most important one. Warm-blooded animals maintain an even temperature through the interaction of two factors: (1) heat generation (thermogenesis) through tissue metabolism; and (2) loss of heat from surface (thermolysis) through radiation, conduction and evaporation of water.

Metabolism is proportional to the superficial area of an animal, but other factors, such as low external temperature, cold baths, wind, humidity and clothing influence metabolism and also modify the loss of heat from the surface of the body.

The recent interest in the "low protein" diet advocated by Chittenden gives the chapters on the influence of protein food an especial importance. Proteins are now definitely known to be constructed of chains of amino-acids. After citing the work of Emil Fischer in building up protein bodies synthetically, describing the products of their hydrolytic cleavage and the methods of the construction of muscle, gland, nerve and other tissue by their synthesis after absorption, Lusk says that any excess of protein ingested is promptly catabolized, or fat may be deposited. He discusses the influence of fat and carbohydrates on metabolism and refers to the experiments of Meissl and Strohmer, Voit, C. Lehmann and Rubner, in which it was shown by experiments on pigs, geese and dogs that the capability of building up fat out of carbohydrates is widespread in the animal kingdom. It is valuable to know that one may diet an obese patient on a food containing little protein and two-thirds of the body's energy requirement without danger of protein loss, the other third of the energy being furnished by the body fat.

In the chapter on the "Influence of Mechanical Work on Metabolism" the author shows that the muscular work does not increase protein metabolism, quantitatively, or change it in character. The power to accomplish muscular work is not usually derived from protein metabolism, but from the combustion of sugar and fat; therefore physical exercise requiring fat consumption without concomitant destruction of protein must be of the greatest value in the treatment of obesity. The increased output of carbon dioxid due to mechanical work is always directly proportional to the work accomplished.

Lusk reports the influence of alcohol on muscular work, as studied by Shumburg and by Hellsten. Both of these investigators found a temporary increase in working power of the muscle, "but after twelve to forty minutes there is a decrease in power which lasts for two hours. No such depression occurs after taking sugar. It is obvious that alcohol is not beneficial when muscular work is to be accomplished."

The influence of training is to make the use of body energy more economical.

Later chapters of this valuable work are devoted to: "A Normal Diet;" "Food Requirement During the Period of Growth;" "Metabolism in Anemia, in Diabetes, in Fever;" "Purin Metabolism—Gout," and finally Chapter XV gives a summary of the theory of Metabolism. The chapters on diet and metabolism in disease are of especial value to the clinician.

The theory of metabolism is a valuable formulation of the known facts and closes with the following sentences: "Living protoplasm metabolizes in accordance with its necessities at the time and never more. A large supply of nutrient materials will not increase cell metabolism. If food is ingested above the requirement of the organism any excess will be retained in the body (unless it has passed out unabsorbed). However clearly formulated the laws of metabolism may be—and many of them are as fixed and definite as are the laws of physics and chemistry—still the primary cause of metabolism remains a hidden secret of the living bioplasm."

The widespread interest in the subject of nutrition at the present time makes this a timely and valuable addition to the literature of the subject.

Hygiene and Morality. A Manual for Nurses and Others, Giving an Outline of the Medical, Social and Legal Aspects of the Venereal Diseases. By Lavinia L. Dock, R.N., Graduate of Bellevue Hospital Training School. Cloth. Price, $1.25 net. Pp. 200. New York: G. P. Putnam's Sons, 1910.

This book, after vividly describing the so-called social diseases, syphilis, gonorrhea and chancroid, historically, clinically and from their sociologic aspects, plunges into the subject of prostitution; giving the history of legislation on the subject. Segregation, regulation and licensing of prostitution are all condemned unsparingly. The author then discusses white slavery and the age of consent, and scathingly arraigns legislators, ministers and the medical profession, as well as the male population in general, for their indifference or positive opposition to measures for the betterment of the condition of women in this respect. She acknowledges, however, that through the efforts of various societies and individuals, principally supported by women, there is recently an awakening on these subjects that promises much for the future, and gives the medical profession especial credit for endorsing and supporting the proposition that continence is not inimical to health. After giving a practical outline of measures for preventing, through prophylactic education in the hygiene of sex, and by other means, many of the evil consequences of what she calls "commercialized prostitution," and the social diseases, the author, who has evidently studied long and thought much and deeply on these questions, advocates as the real solution of the problem equal standards of purity for the two sexes and woman suffrage. However one may feel about the latter conclusion, the book certainly presents in a strong manner the truth about evils which cry aloud for some solution, and should help in bringing about the enlightenment of the public. It will undoubtedly bear a goodly share in arriving at whatever measure of success is attained in that direction.

The Expectation of Life of the Consumptive after Sanatorium Treatment. By Noel D. Bardswell, M.D., Medical Superintendent, King Edward VII Sanatorium. Cloth. Price, $1.50 Pp. 130. New York: Oxford University Press, 1910.

The problem of life expectancy in the consumptive class requires for its solution accurate life-histories of a large number of patients subsequent to their discharge from sanatoria. Such histories have not been available, partly because of the difficulty of keeping in touch with discharged patients and partly because results have not confirmed the prophesies of some ardent advocates of sanatorium treatment. Dr. Bardswell has made a small but valuable contribution in this record of 241 cases of tuberculosis, which includes 62 cases of incipient disease, 95 of moderately advanced and 84 of far-advanced cases. He believes that his statistics indicate that a permanent recovery may be expected in from 70 to 80 per cent. of cases of early consumption, in from 40 to 60 per cent. of moderately advanced cases and in 8 to 10 per cent. of the far advanced cases. If like statistics from many observers can be steadily collected and critically and impartially analyzed, we may, in time, arrive at the consumptive's expectation of life and at the same time ascertain the true value of the sanatorium and other treatment.

A History of the London Hospital. By E. W. Morris. Cloth Price, $1.75 net. Pp. 296, with illustrations. New York: Longmans, Green and Co. [1910].

Those who imagine from the title of this book that it is a dry and prosy chronicle of facts relating to the institution named in the title will be agreeably surprised. The author has really painted a panoramic picture of the progress of medicine and surgery from the time of the founding of the London Hospital, in 1740, to the present time. More than that; he has given in interesting detail the conditions obtaining among such of the poor and needy as, when ill, applied to this hospital for relief. The book is indeed a history, and a most instructive one, of British medicine, with the London Hospital for a central theme. To read it is to admire the magnificent pioneer work of those who have gone before and to be thankful that one is living in the twentieth century. Having read it, one has a clearer conception of what the British system of supporting hospitals by voluntary contributions means.

THE DISEASES OF INFANCY AND CHILDHOOD. Designed for the Use of Students and Practitioners of Medicine. By Henry Koplik, M.D., Attending Physician to the Mount Sinai Hospital. Third Edition. Cloth. Price, $5. Pp. 944, with 233 illustrations. Philadelphia: Lea & Febiger [1910].

This edition is considerably enlarged, thoroughly revised and brought up to date. The book reflects the mature experience of a keen observer. It is reliable throughout, is abundantly illustrated, and is, in every way, well balanced, both as a textbook for the student and as a reference book for the general practitioner. The chapters on certain subjects with which the author is perhaps most naturally associated in our minds, such as those on meningitis, the acute infectious diseases, etc., are especially noteworthy. The chapters dealing with infant-feeding and nutritional disturbances in infancy reflect to a large extent and in a very refreshing, though conservative, manner the recent advances in our knowledge of that subject. The book can be safely recommended as one of the best exponents of American pediatrics.

THE CONQUEST OF CONSUMPTION. By Woods Hutchinson, M.D., Author of "Studies in Human and Comparative Pathology," etc., and Clinical Professor of Medicine, New York Polyclinic, etc. Cloth. Price, $1 net. Pp. 138, with illustrations. Boston: Houghton Mifflin Company, 1910.

Woods Hutchinson is a sort of hygienic John the Baptist and goes forth preaching in the wilderness of the lay world. He discusses the enemy—tuberculosis—what happens to the bacillus in the human body, the weapons for the fight against the enemy, how to get fresh air and sunlight (he considers food in reality as the greatest foe of consumption), discusses intelligent idleness, the question of the camp and country, the financial question, the expense of treating tuberculosis, the matters of climate and health and ends with specifications for the open-air treatment of tuberculosis at home. The book is hopeful, encouraging, and can be heartily commended.

PRESCRIPTION WRITING AND FORMULARY. By John M. Swan, M.D., Associate Professor of Clinical Medicine in the Medico-Chirurgical College of Philadelphia. Flexible leather. Price, $1.25 net. Pp. 185. *Philadelphia. W. B. Saunders Co.*, 1910.

This is an excellent little manual. Owing to the multitude of private formulas and "ethical" proprietary remedies, the average student who graduates is unable to write a prescription correctly. This little manual takes up the construction of prescriptions. Latin forms and terminations, the Pharmacopeia, weights and measures, doses, abbreviations and incompatibilities and has an appendix of more than 100 pages devoted to a formulary for various conditions, alphabetically arranged.

THE INFLUENCE OF STRONG, PREVALENT, RAIN-BEARING WINDS ON THE PREVALENCE OF PHTHISIS. By William Gordon, M.D., Physician to the Royal Devon and Exeter Hospital. Cloth. Price, 7 shillings 6 pence net. Pp. 108, with illustrations. London: H. K. Lewis, 136 Gower St., W. C., 1910.

This work shows an enormous amount of detail work and it is regrettable that it can be of little value save to the statistician. Few conclusions of value are made—the most important probably being that the prevalence of strong rainy winds appears to be remarkably associated with the increased prevalance of tuberculosis, while the absence of such winds appears to correspond strikingly with the rarity of the disease.

Society Proceedings

AMERICAN ACADEMY OF MEDICINE

Fifteenth Annual Meeting, held in St. Louis, June 4 and 6, 1910

The President, DR. JAMES H. MCBRIDE, of Pasadena, *in the Chair*

The officers elected were given in THE JOURNAL June 18, p. 2053.

Report of Committee on Essential Subjects to Be Taught in a Medical School

DR. EDWARD JACKSON (Chairman), Denver: A most urgent present need regarding medical education is careful consideration of just what matter should be placed before the student by the teacher of each subject in the medical curriculum. The paramount need is wise selection. The giving to each individual teacher absolute control of the matter of selection and of a certain portion of the time and energy of each medical student, with little attempt to closely co-ordinate his own with the work of the different departments, has developed a state of pedagogic anarchy. A proper corrective would be a general discussion in which the suggestions of the teacher of one branch should be criticised by the teachers of the other branches.

In this connection it would seem advisable that the Academy should devote a mid-year conference, held probably in connection with the Association of American Medical Colleges, to the discussion of this general subject. The underlying thought of papers presented at such a conference should be to seek an agreement as to the relative order of the importance in the training of the topics to be taught in a particular branch. In making such selection of topics certain general needs and facts must be acknowledged as fixing their relative values in the required course. For example:

The general developmental value of the topic, especially in the fundamental branches. Some natural order of development, and the practicability of studying certain things better in college while others may be as well or more readily studied afterwards. The need of mutual understanding among physicians in giving professional unity; the appreciation by each of work in all branches with ability to appropriate that which can be made useful in one's own work. The facts that every graduate should be fitted to render some definite practical service to the community before he is heralded as a doctor of medicine, and that the required undergraduate training is the beginning of a process normally to continue throughout the whole professional life.

While, for development in conformity to individual tastes and desires, some freedom must be given from the beginning, the full latitude in this respect must be left for the postgraduate period of development.

Educational Principles Involved in the Combined Course in Arts and Medicine

DR. A. ROSS HILL, University of Missouri, Columbia: The arrangement by which a student pursues general courses in letters and science for two or three years, then for a year or two follows about equally fundamental courses in the sciences of anatomy and physiology with vocational or professional motive to stimulate his interest, but with an emphasis on the spirit of discovery and on scientific method, then spends two or more years in specifically professional training with the hospital clinics for his laboratory, seems to recognize the normal development of special interests and the gradual growth of professional insight toward that maturity of judgment which is demanded of even the beginner in the field of medical practice; while it saves the immature student from the pursuit of that narrow practicality which forever limits his power to think and his ability to grow and adapt his judgment to new conditions and new scientific discoveries. To object to it on the ground that it means counting one and the same course to two degrees is purely formal and arbitrary and would be considered puerile were it not for the educational standing of those who offer the objection. The severest criticism that seems at all fair to pass on the combined course is that it is good enough for those who will not adopt a better plan, the better plan being the requirement of the A.B. degree of candidates for entrance to the school of medicine.

The ultimate solution of the problem of how to secure sufficient breadth of preliminary training for the medical student without unduly prolonging the period of preparation seems to lie in the improvement of our elementary schools, which are now wasting about two years of the average pupil's time. When the present standard for the A.B. degree will have been attained by normal, unretarded youth at twenty instead of twenty-two years, the requirement of an A.B. degree, representing in the main humanistic culture, will become a natural standard for admission to schools of medicine, and the combined course will become inadvisable. Till then it seems not only to furnish a reasonable standard of requirement, but to be based on sound educational principles.

Is the Profession Losing Its Grip?

Dr. Charles McIntyre, Easton, Pa.: Physicians of to-day do not occupy the same relation to the world of education and science as they did in the middle of the last century. Many doctors of medicine were teaching general science and other subjects in colleges in the decade 1841-1850, while to-day in these colleges not a single M.D. occupies a corresponding chair. On the other hand, it is a frequent occurrence to find men without the M.D. degree holding prominent chairs in medical colleges, serving as directors of health departments of our municipalities and writing school physiologies. The question is raised, is not the condition due to the narrowing influences of the early specializing in the present scheme for medical education? Professor Dewey, of Columbia, is quoted as saying that much of the science teaching has failed to be a means of liberal education because of the faulty method of many of the teachers, and the assertion is made that the temptation to pursue the faulty method is greater in the medical college than in the undergraduate department. It may, perhaps, be said that the present system of education is not a success because its promoters are desirous of so many changes requiring more time. It seems pertinent to question the correctness of the principle of the present scheme, and to suggest that more attention be paid to the preliminary general education than now, teaching thoroughly the rudiments of medicine in the medical course, and transferring much that is now attempted to elective postgraduate work.

DISCUSSION

Dr. E. P. Lyon, St. Louis: My own observations have shown me that the man with the two years' training, the man who takes six years of college and medical work, is able to advance to a much higher degree of attainment than the man who goes into the medical school from the high school. I believe the combined course is the ideal toward which we should all work in medical education. I agree with Dr. Jackson in his reference to a state of "pedagogic anarchy" in some medical schools. It would seem that there ought to be a medical normal school in which men could learn how to teach. In my opinion the main reason why men who devote their entire time to the fundamental sciences should be encouraged to teach these subjects rather than practitioners is that most of them are graduates of laboratories in which they have had to do some teaching and are men pre-eminently interested along this line.

Dr. Thomas D. Davis, Pittsburg: The trouble with our medical educational institutions to-day is that they are trying to make too much out of students and demanding of them many things that are impracticable. No one should leave college with the idea of being equipped as a specialist. That is the work of the post-graduate school.

Dr. J. E. Tuckerman, Cleveland: The man who would be fitted by temperament, by natural ability, to take up the study of medicine has no need to waste, as he now does below the college course, two to four years. We must begin far down in our educational system to put it on a proper basis. If we say that laboratory teaching should be done entirely by laboratory men, we run into another difficulty. I have known efficient chemical laboratory men to be ignorant of clinical facts concerning drugs about which they were teaching.

Shall the Ph.D. Be Granted for Work in the Surgical Sciences?

Dr. Arthur E. Hertzler, Rosedale, Kan.: The functions of a university are humanistic, scientific and practical. The practical can reach its highest perfection only when based on the humanistic and the scientific. The science of medicine is a department of biology. Applied medicine is but the discovery and application of forces which negate the counteracting forces as revealed by pathology. Chemistry, anatomy, physiology and pathology are now accorded academic recognition. With men and equipment equal to those now available for the fundamental branches, surgery would reach and maintain the same high scientific level. So-called practical medicine is but an apology for the lack of scientific methods, with the introduction of scientific methods. Practical medicine will give place to the "applied science of medicine." With the granting of university rank the science of surgery will share the benefits of definite organization and will profit by the humanistic spirit of the university, and will encourage picked young men who desire to devote themselves to scientific careers to select surgery as the field of their activities as the fundamental branches have in the past.

DISCUSSION

Dr. Henry B. Ward, Champaign, Ill.: The answer to Dr. Hertzler's question must be traced to present conditions. For the granting of the Ph.D. in the surgical sciences there must be in the curriculum opportunity to do research work. The intensiveness also of an institution is a factor. The man who would take the degree must have the opportunity to go far beyond the limits of ordinary instruction. How many of our colleges are prepared to offer this opportunity? In the matter of adequate teaching, the man who shall successfully direct the work of the student for the degree of Ph.D. must be one who has the vision of the prophet, one who seees beyond the limits of the known, who has sufficient grasp and insight into the future to indicate to his disciple the successful lines of attack in mastering the unknown. And, while results depend largely on environment, fundamentally they depend on the individual student, and the question ultimately is one of mental caliber. Personally, I confidently look forward to the time when the medical schools of this country will not only in surgical sciences but in all branches offer the Ph.D. degree, and will carry their students to the point where they will thoroughly deserve that degree. Then the contributions of America to the advancement of medicine will be worthy of a great nation.

Dr. Henry B. Hemenway, Evanston, Ill.: I hope the day is far distant when Professor Ward's proposition will come true. I would have the degree of M.D. stand for the very best we can get in medicine, allowing to those who have achieved something extraordinary an honorary degree. Let it be a purely honorary matter, not a matter of commercialism. I do hope, however, to see the time when the colleges all through the land will give a training which would be equal to that which might command the Ph.D. degree.

Correlation of School Health Supervision With Other Health Agencies

Dr. Ernest B. Hoag, Berkeley, Cal.: School health supervision ought to be under the control of the Board of Education and not under the board of health in all places, with the possible exception of larger cities with well organized governments. There ought to be a cooperation between the school health officers and the city health officers that there need be no duplication of effort. It is usually possible to bring various health organizations such as the associated charities, the medical dispensaries, the dental dispensaries and certain social welfare societies under one general organization. In Berkeley all of these health agencies have been brought together under one roof with great economy of effort, effectiveness, time and money.

The School System and the Child

Dr. A. L. Benedict, Buffalo, N. Y.: In reference to the frequent condemnation of the modern system of education, it may be said that a system that has been increasingly bad should manifest itself by an increasing mortality in the rising generation. On the contrary, there has been a decided decline of the death rate and an increase of the average longevity of about seven years in a generation. Much of the reputed ill-effects of our school system may be attributed to extrinsic causes. Many children are insufficiently fed and clad, and are overworked by their parents. The criticism that the school system treats the children wholesale instead of considering individual capabilities is but a reflection of the requirements of life in a republic. While in large cities the establishment of special courses for those above and below the average capability might be advisable, the present standards represent fairly well the capability of the majority of pupils. The school has been of immense benefit also in having corrected purely physical defects, the cause of dulness. The verdict of the child himself is distinctly favorable. Even proportionate to the population the high school attendance has doubled or quintupled in the last 25 years. This could scarcely be the case if the grammar school were either physically injurious, cruel, or inconsistent with the real needs of the people.

DISCUSSION

Dr. Thomas D. Davis, Pittsburg: We do not give the public schools the high praise they deserve for what they accomplish in the small amount of time they have with the scholars. The charge is often made that the children are burdened with overwork, but I could cite instances showing that the strain is put on the child at home, and the school is wrongly charged with the nervous break thus wrought.

Dr. Helen C. Putnam, Providence, R. I.: How we look at the public schools depends on what we consider they are for. We consider that they are to make good citizens. The parents have been criticized very severely, but the public schools did not educate them to become good parents; consequently their children are not being well trained. That is one way in which the public schools are far behind the needs of the country. We have 500,000 tramps, and over 90 per cent. have been in our public schools. Why are they tramps if the public schools did their duty by them? We have a large class of paupers unable to support themselves and only a small proportion able to read and write. There is something about the education of the masses in this country that is at fault. I am entirely willing to grant a lot of good intention with regard to the public schools, but until we can supply institutions that will give teachers a better training, and have appointed committeemen who instead of being politicians, are up to the standards in their ideas with regard to education and what education is for, I think we must strive with every faculty we have to try to improve our public schools.

Dr. Leartus Connor, Detroit: The importance of manual training in the schools ought to be emphasized. The severest criticism I have to make of the whole school system is that it magnifies the power of book knowledge to the detriment of the practical knowledge that enters into the life of a citizen.

Dr. Henry B. Ward, Champaign, Ill.: I agree with Dr. Putnam that the schools are not doing what they ought, but that is not the fault of the schools. When we consider that the child spends one-tenth of his time under the influence of the teacher, it is unreasonable to charge the shortcomings in the case to this influence and ignore the other 90 per cent. of influence. The fundamental difficulties can never be righted exclusively by the school. There will be required the influence of the home to make the product of America higher and better in the next generation.

The Social Aspect of the Gonococcal Infection of the Innocent

Dr. W. A. Newman Dorland, Philadelphia: Discarding the statistics of the alarmists, who estimate that as many as 90 per cent. of pelvic inflammatory cases in women are due to the infection, 50 per cent. may be attributed to this cause. Not only are there innocently infected women, but there has been marked increase of the infection in little girls. It is the concern of the medical profession to exert greater care in the "social" treatment. Social status does not afford immunity and social status does not guarantee personal purity. While the time may not be ripe for the state to require a medical certificate, the young woman's parents may demand a clean bill of health. Especially should the profession avoid the fallacy that health and continence are not compatible. By no means during the presence of the disease should a gonorrheic marry. The disease is curable; when cured there is no danger of communication.

Ocular Disease in Hereditary Syphilis

Dr. S. D. Risley, Philadelphia: More than 60 per cent. of all cases of iritis applying for treatment are due to syphilis, and at least 35 per cent. of all blindness is the result of gonococcic infection during parturition.* The vast majority of cases of interstitial or parenchymatous keratitis are unquestionably due to hereditary syphilis. Thus syphilis stands to-day, as it has stood for generation after generation, the darkest blot on the fair escutcheon of our Christian civilization. Attention should also be called to the very large group of patients suffering from chronic forms of eye disease which are difficult to classify, but which are doubtless due to impaired general nutrition, the result of mild or less virulent doses of the infection.

The Social Plagues and the Public Schools

Dr. Ira S. Wile, New York City: The state in compelling attendance at public schools tacitly assumes the responsibility of safeguarding children from all contagious and preventable diseases communicable at school. Books on school hygiene and medical inspection of schools do not refer to venereal diseases as part of a school problem. Medical examination of teachers demands more attention. Janitors, scrub women and attendants are known sources of venereal infection. Of the new admissions to schools for the blind in 1907, 25.21 per cent. were due to ophthalmia neonatorum. To educate the blind costs eleven times as much as to educate one with normal sight. The school problem consists principally in prevention by abolishing common drinking cups, towels, pencils, sponges, etc. Toilet facilities must be improved. Examination of genitals must include microscopic examination of mucus or pus. The boards of health should make such examination gratis. Children require better hygienic education in order to protect themselves when puberty develops.

The Black Plague and the Educational Remedy

Rev. George R. Dodson, St. Louis: In fighting the black plague the first thing is to turn on the light. At present we instruct children in many matters of minor importance and keep from them the knowledge that would save them from their greatest dangers. In conveying this instruction the simple, direct method is the best. There is nothing so eloquent as the terrible facts. It is essential that the people should initiate and carry on this reform, for only those social movements which have behind them popular conviction "stay put." Such legislation as may be enacted should aim rather at enlightenment and educational effects than at considerable direct results. The public will respond as soon as it is made clear that venereal disease destroys not only the dissolute, but that in immense numbers it blights the lives of the innocent. Furthermore, the teaching that saves from the black plague will also raise the whole subject of the transmission of life from the low plane it occupies in the thoughts of many, and the by-product of our instruction will thus be of almost as great value as the public health which is the main aim.

OHIO STATE MEDICAL ASSOCIATION

Sixty-fifth Annual Meeting, held at Toledo, May 11-13, 1910

(Concluded from page 155)

Two Cases of Heart Block

Dr. L. C. Grosh, Toledo: One case illustrates block at the auriculoventricular juncture, and the other at the sinoauricular juncture. By heart block is to be understood an imperfect conduction of the impulse from one cavity of the heart to another. In man two forms have been found: a failure of some of the beats to pass the block, and when none of the impulses are conducted from one part to another. Either of these may result from interference with the vagus center; any interference with the vagus nerve or its terminals, or by changes in the myocardium. The first case was under observation for four years with unusual opportunities for registering both the venous and arterial pulse. The condition was changed from complete block to normal two different times. The blood pressure was at all times over 200. There was a complete series of transitional forms from the 1-1 rhythm in which conduction was adequate, through 3-2, 2-1, 5-2, to 7-3 and 8-3 rhythm, and it is difficult to state at what point the ventricle became independent of the auricular tutelage. The second case, that of a man showing emaciation, anemia and a palpable tumor connected with the pylorus, was under observation a year, during all of which time the arrhythmia persisted without fundamental change until death. A microscopic examination in the area described by Heath and Flack revealed marked proliferation of the connective tissue and minute plaque-like calcareous deposits.

DISCUSSION

Dr. J. E. Greiwe, Cincinnati: The interesting feature of the analysis is that the muscular tissue of the heart must be considered as divided into two classes: the tissue which has to do with contraction and expansion of the blood vessels, and the tissue which is associated with the function of conductivity. There is a definite path for the stimulation of conduction. It has been found that this does not pass directly to the ventricular wall but into the papillar muscles, and on to the muscular fibers from above downward and then back to the heart. If there is a sclerotic process of the heart, a great deal depends on the seat of the trouble. In acute myocarditis there may be no change in the rhythm of the heart; and where there is marked change in the rhythm there may be no extensive myocarditis.

Dr. L. C. Grosh, Toledo: The work done from a physiologic standpoint is of great importance. The rather peculiar tissue that is gathered into the so-called bundle of His has had some of the primary functions of the heart attributed to it, and while this is more or less speculative, I feel that the heart has developed up around this peculiar primary cardiac canal.

Diagnosis and Treatment of Early Pulmonary Tuberculosis

Dr. J. P. DeWitt, Canton: The fact that present methods of treatment will effect a cure in tuberculosis in ninety to ninety-five per cent. of cases if applied early should stimulate all medical men to become competent to make an early diagnosis. Inspection, palpation and percussion are of little value in early cases, and information must be had through auscultation. One should proceed to the use of tuberculin to prove the diagnosis. Close observation will often reveal a local reaction (e. g., by the use of Hay's laryngoscope) without general reaction occurring. The inunction of the tuberculin ointment of Moro or the cutaneous test introduced by von Pirquet is usually employed first; if reactions do not occur, the old tuberculin of Koch is injected subcutaneously. After gradually increasing the dose from one-tenth to ten milligrams, if no reaction has occurred it is quite certain that the patient has not early tuberculosis. Few patients in limited financial condition ever recover from well-developed tuberculosis. Observation will show that many supposed to have been cured by rest and feeding relapse. A cure is due to the infected organism establishing an immunity to the tubercle bacillus. I have never seen harmful results from reactions, but often marked improvement follows where previously the patient was not doing well. If there is a temperature of 100 degrees or over the patient is put to bed until the temperature is normal. Patients immunized with tuberculin do not develop complications of the larynx, glands or bowels, and very few relapses are noted, while patients apparently cured without tuberculin frequently relapse and develop complications. Return of the bacilli proves that the patient was not cured. Patients given specific treatment, plus hygienic treatment maintain their immunity to the tubercle bacillus and its toxin.

DISCUSSION

Dr. R. P. Daniells, Toledo: The many different dilutions of tuberculin put out by the various companies have made its use apparently so easy that it has become a dangerous thing, because not given carefully, and because the person giving it does not understand how it is being given and why, and he does not watch the patient. It is one of the most valuable aids in the treatment of tuberculosis, if given carefully. The skiagraph is another important aid in diagnosis, and shows some things absolutely impossible to learn in any other way—the healed tuberculous lesions.

Dr. John North, Toledo: The tuberculous pulse differs from every other, furnishing a means of early diagnosis. This peculiar pulse will occur two years before the case can actually be diagnosed by physical tests. If a patient has the full proportion of calcium in the body he is immune from tuberculosis. The tuberculous patient eliminates lime, he cannot assimilate it, and the things that give the best results are milk and eggs, both of which contain a large proportion of calcium salts. Put them in condition to assimilate by hydrochloric acid, and they improve. The pregnant mother has tuberculosis because she has taken the lime from her body to build up the body of the baby.

Dr. L. A. Levison, Toledo: In using the test of von Pirquet if the reaction is not at all positive, if one will wait until the next day and inject a small dose subcutaneously, there will be a reaction, even when the dose is not enough to induce a rise of temperature. This is valuable in cases where it is not advisable to use the old methods of Koch.

Dr. William E. Hover, Lima: All people who have cold hands and feet, who dread to sit in a draft, who will not eat beef steak cooked rare, and who cannot or will not take milk, should be looked on as having incipient tuberculosis and treated accordingly, whether they react to the test or not.

Dr. Oscar Berghausen, Cincinnati: In considering the primary pathology it is often found that the infection occurs from a primary bronchial lesion. It must be borne in mind that there may be a primary lesion in the kidneys, and if this is suspected, care must be taken not to set up a complication through the use of the tuberculin test.

Dr. J. P. DeWitt, Canton: The main point I wished to bring out is that patients apparently recovered from tuberculosis by the use of rest, food and fresh air, are not well and will react to tuberculin, and a great many do relapse; but patients who have in addition immunizing doses of tuberculin have a different appearance, and they do not relapse.

The Treatment of Pneumonia

Dr. James L. Tracy, Toledo, sought to emphasize the importance of studying the treatment with reference to the biology of the disease. The cells in the lungs whose functions are so directly impinged on by the diplococcus call to their aid and defense the functions of co-ordinate and interdependent cells, and from these in turn go out calls for organic functional assistance, and that functional assistance which is so promptly rendered is made up of those abnormal functional processes by whose functions is constructed the lymph dam of diplococcus infection; and the specific characteristics of the lymph dam for the diplococcus shows a prearranged preparedness of systemic integrity for resistance to that particular infection. None of the emergency processes can be absent from the general plan for systemic defense without rendering the other processes ineffective. They fit one into the other as the physiologic processes fit one another, and together these unusual organic functional processes are, biologically, as really and intelligently as defensive of systemic life as are the usualy organic functions of the body, biologically, constructive and conservative of systemic life. This being so, it is therefore wise, and hence scientific treatment of pneumonia, at the first visit, to confine the efforts at helpfulness to the patient to the furnishing of sustenance to these organs which are so excessively functionating; the treatment must be hygienic and dietetic.

The Protection of Child Life

Dr. C. O. Probst, Columbus: Human life, which means productive energy, should be regarded as the main one of our natural resources. The state could greatly extend and perfect measures that have already in a limited field proved effective, as the control of the milk supply, the education of dairymen and parents. It could place one or more honest inspectors in each county to enforce its requirements, and might have a traveling dairy exhibit along the lines of the tuberculosis exhibit. More progress would be made if no further effort were made to "teach old dogs new tricks," but attention should be devoted to the training of the school children in hygiene and sanitation and physical education. This would mean a new man in school life, a school physician; it would mean school supervision, not school inspection.

Most of the school books could be utilized to teach certain health subjects. Sums in arithmetic could deal with sanitary problems as well as interest or land measurement. In teaching geography, maps might show the relative prevalence of tuberculosis in different countries, and in history the great plagues could be recalled to show the blessings of improved sanitation and vaccination. If great deeds are to be chronicled to inspire patriotism, why should the heroes of godless wars be selected rather than the heroes of life-saving, preventive medicine, who have laid down their lives in battling against or searching for the cause of pestilential disease? If presidents,and members of congress,legislatures,councils and school boards had themselves been given such instruction, efforts for a national health department would be vastly easier of attainment. Education in matters of health should be begun with the grandparents of children to be born fifty years hence.

Three Years of Serum Therapy in Epidemic Cerebrospinal Meningitis

Dr. William S. Chase, Akron, Ohio: In the serum-treated cases, after one or two subdural injections, the cerebrospinal fluid becomes clearer. Microscopically, there appears a preponderance of intracellular meningococci and the nuclei no longer take the stain well. There is a decrease in the leucocytes in the spinal fluid and also a fall in the general leucocyte count. In the cases which react favorably, within twenty-four hours the temperature falls, frequently to normal; all symptoms of hyperesthesia are greatly reduced and the patient passes from a period of wild delirium to one of perfect quiet and complete consciousness. Subsequent exacerbations in these cases are less so severe and improvement follows other injections. It is interesting to note that the neck rigidity and the Kernig sign are usually the last symptoms to disappear, and frequently continue well into convalescence. The average duration of the disease in the serum-treated cases is about two weeks, as against five or six weeks of tedious illness in those which went on to recovery under previous methods of treatment. Complications are practically suppressed. In the cases injected early deafness is common.

The earlier the serum is given, the greater is the chance of recovery. Work done in the French epidemic last year suggests the strong probability that cases treated with the subdural injections in the early prodromal stage may be aborted. Lumbar puncture should be performed as a diagnostic measure in all suspected cases.

DISCUSSION

Dr. Zinninger, Canton: Flexner has been wise in restricting the use of the serum to men who could confirm their diagnoses by scientific methods. If there is to be improvement in the use of the serum, either it must be in its production or in the technic of its administration. One of the most interesting things to consider is whether there are different strains of the diplococcus, and Flexner is working on this question now. It is known that this is true of other cocci, and those following the methods of vaccine treatment know that an autogenous vaccine is superior in nearly all cases to that made from the stock vaccines.

Exudative Erythemas and Their Visceral Manifestations

Dr. Mark R. Brown, Cincinnati: My paper refers to those involvements of the skin characterized in one instance by serous exudate (angioneurotic or localized edema); in another by serous exudate plus hyperemia (urticaria); in a third by serous exudate plus hyperemia and hemorrhage (erythema multiforme); and in a fourth by exudation or extravasation of erythocytes (purpura). While any of these conditions may present itself alone, their not infrequent relationship with arthritis or with certain serious and well-marked visceral lesions, or both, renders the symptpom-complex interesting to internists. In different attacks in the same individuals, different manifestations or combinations may be present and give rise to varied diagnoses—Schoenlein's disease, Henoch's purpura, angioneurotic edema or urticaria—all of which may have been correct in so far as that particular attack was concerned. As to internal changes, the most important are those involving the heart, as endocarditis and pericarditis; the kidneys, as nephritis; the gastrointestinal crises, and hemorrhages. The symptom-complex then promises a number of skin lesions, a variety of internal disorders and an arthritis of varying intensity.

In five of seven cases arthritis was present, and in the two remaining arthritis had been present in previous attacks. Occasionally there is synovitis or periarticular inflammation; but one is impressed with a relationship to articular rheumatism, particularly as there was, in several instances, a preceding or coincident tonsillitis. All patients with arthritis had some fever. Sweating was not present. Eruption was present in considerable variety. In all but two there was purpura hemorrhagica, in three localized edema, in one urticaria, in one erythema nodosum, in two erythema multiforme, in one vesiculation. In several, different cutaneous manifestations occurred at the same time, in others there were different eruptions at different attacks. There were two cases of acute endocarditis, two of acute nephritis and in two others hematuria. In one there was chronic nephritis from the onset, but no blood was found. In three there were abdominal cramps, in one pleurisy with effusion, followed by dry pleurisy on the other side.

Pulmonary Manifestations of Syphilis, with Report of Cases

Drs. H. W. Dachtler and R. P. Daniells, Toledo: During the past year, in examining about ninety patients for pulmonary tuberculosis, and studying the condition of the lungs with the help of the skiagraph, most of the cases were found to be uncomplicated tuberculosis, a few were mixed infections of tuberculosis and syphilis, while six cases came under observation which proved to be uncomplicated syphilis of the lungs. The patients came or were sent because they were losing weight and had a slight fever; some had a little dry cough; all were easily fatigued, and they, or members of their families suspected beginning consumption. These six cases are reported because they suggest that a syphilitic condition occurs more frequently in the lung than is usually suspected, and because it closely resembles the early stages of pulmonary tuberculosis. In all the cases tuberculosis has been eliminated first by no reaction to 12 mg. of Koch's old tuberculin given hypodermically; and second, by no signs of tuberculosis demonstrable in the skiagraphs. Moreover, syphilitic infection has been proved either by a direct history of infection or by a history of miscarriages with other syphilitic signs and symptoms, and a rapid improvement on antisyphilitic treatment, and in one case by the Wassermann reaction. From the study of these cases, we believe that a syphilitic condition of the lungs occurs more frequently than is generally suspected, and that without doubt it is often treated for pulmonary tuberculosis.

Intravesical Operations, with Report of Cases

Dr. Charles M. Harpster, Toledo: With the cystoscope we are able to see many conditions rather than diagnose them by symptoms, such, for instance, as papillomata, sarcomata and carcinomata, foreign bodies of all sorts, ulcerations and their character, cystitis and its mode of infection, prostatic and pericystic enlargements, the condition of the ureteral orifices, activity of urinary secretion, absence of either kidney, double ureter on one side, hematuria following renal colic, tuberculosis of renal carcinoma, and various infections of kidney and bladder. In time to come the cystoscope will be used more in catheterizing the ureters, in applying suction or hyperemic treatment to bladder conditions or in drawing urine from the ureter and in making applications to diseased areas, in the removal of foreign bodies, removal of growths by snare, incision of strictured ureters or their dilatation, and many other operations and procedures. Ureteral catheterization is of service in showing the patency of the ureters, in obtaining separate urines and in finding calculi, crystals, epithelium, casts and tuberculous material and determining the competency of either kidney. With a bismuth fused catheter *x*-ray confirmation of diagnoses may be made, and the catheter may be used during gynecologic operations to prevent injury to the ureter, as is done by Olshausen and others. The Luys separator is useful for diagnostic purposes where the condition of the bladder has been previously determined by the cystoscope. Errors which may arise with either the catheter or the Luys separator are due to faulty instrumentation, reflex oliguria or polyuria caused by the instrument or the collection of urines at inappropriate times. Two factors are necessary with catheterization to give accurate quantitative results—a catheter with a terminal opening, and Albarran's method of methylene blue injection into the catheter. In prostatic enlargements of old men in whom general or spinal anesthesia are contraindicated the technic and instruments of Goldschmidt are useful. Under a 2 per cent. solution of novocain the obstruction, especially if a bar or medium projection, can be incised under the guidance of the eye. With the old Bottini instrument or the Freudenburg modification this could not be done. Multiple incisions cause contraction of the gland. One out of every four cases of prostatic hypertrophy is cancerous. This method of treatment offers hope of preventing cancerous development by relieving increased tension and pressure on the gland and decreasing the irritation from residual urine. If it will stay or prevent cancerous development in even a small number of cases in the inception of the condition its use must become a fixed proceeding in surgery.

AMERICAN NEUROLOGICAL ASSOCIATION

Thirty-sixth Annual Meeting, held in Washington, D. C., May 2-4, 1910

(Concluded from page 158)

Myositis Fibrosa Following Nervous Breakdown

DR. JOHN K. MITCHELL, Philadelphia: A nervous breakdown from overwork was followed by an attack of fever of unknown origin, with great prostration. Four months later a stiffness in the extensors of one thigh was noticed. A like stiffness and hardness successively appeared in muscles of other parts. This increased in degree until the patient was almost crippled. A portion of muscle excised during life exhibited widespread fibrous degeneration, the muscle fibers being in some places replaced by fibrous tissue, in others pushed aside by it. In cross-section radiating striæ, apparently of fibrous tissue, are seen. The patient improved under treatment.

Friedreich's Ataxia

DR. WILLIAM G. SPILLER, Philadelphia: In this case, in addition to the usual findings in the spinal cord, the peripheral nerves were greatly degenerated; recent degeneration detectable by the Marchi method was seen in some of the muscle fibers, and the cerebellar nuclei showed alteration of the nerve cells. Many naked axis cylinders were detected by the Bielschowsky stain in the columns of Goll, which by the Weigert hematoxylin stain appeared almost completely degenerated. Friedreich's ataxia is not a degeneration confined to the spinal cord or cerebellum, but is the result of implication of the entire central and peripheral nervous systems.

DISCUSSION

DR. E. W. TAYLOR, Boston: In one case which I studied there was a striking degeneration of the cerebellar tract and of Gower's tract. I would ask whether Dr. Spiller was able to trace this degeneration of Gower's tract into the cerebellum, and whether anything has been done toward tracing Gower's tract and the cerebellar tract toward their terminations.

DR. B. SACHS, New York: The distinction between Friedreich's ataxia and amaurotic family idiocy is interesting. In hereditary ataxia we evidently have an involvement chiefly of tracts of peripheral structures, and no doubt there is some cellular involvement as well, while amaurotic family idiocy is a purely cellular disease. Some years ago these cases were spoken of as cases of arrested development. These family diseases would not occur if there were not some vital defect in the germ plasm. That vital defect makes the organism less resistant to extraneous influences or to influences within the body than it would be if this vital defect in the germ plasm did not exist. I do not believe that any family disease can be due to an extraneous toxic or infectious agent, but an infectious agent that is formed within the body itself is conceivable, particularly if you admit that the injury done to the germ plasm in the first place makes the various structures of the body less resistant to poisons formed within the body itself.

DR. W. G. SPILLER: The Wassermann reaction was not taken, but there were no clinical manifestations of syphilis. The pathology shows no round-cell infiltration, such as is characteristic of the nervous system. Gowers' tract was not degenerated, although in many cases of Friedreich's ataxia it has been. Cellular changes are not usually found in Friedreich's ataxia, according to report. The nucleus dentatus in this case showed decided cellular changes. There were also some changes in the cortex.

Freud's Analytic Method

DR. JAMES J. PUTNAM, Boston: In so far as Freud has shown us a valuable means of studying the processes which go on unconsciously within our minds and the respects in which they lead to traits of character and temperament, it is difficult to see how any one can fail to recognize the importance of his work. Most of the criticisms have come from persons who have failed to verify his conclusions. However, the more carefully and thoroughly the method is applied, the more accurately the conclusions derived from it will be found to coincide with those laid down by Freud and others who have followed in his footsteps. It is obvious that the talents and interests of neurologists are not all of the same sort, and for those to whom the study of the mind in health and in disease appears the most important portion of the physician's work, the contributions of this relatively new field are certain to seem of marvelous promise and of immense practical importance.

DISCUSSION

DR. G. L. WALTON, Boston: One important difference between these memory pictures and those of the waking life is the inability of the dreamer to measure time and space; but the main distinction lies, perhaps, in the absence of goal ideas and of the power of control which enable us in our waking hours to guide our thoughts more or less successfully in definite channels. The associations by which these pictures are assembled will vary with the individual and be tinged by his emotional tone, but to read into them, however ingeniously, the fulfilment of desires is to strain a point, and to substitute a preconceived notion for the study of facts. To credit mere memory pictures, distorted at that, with being symbols is unduly to glorify the dream state—I should perhaps rather say unduly to debase it when the symbols are of the character which permeates the works of this author. The reproduction of a dream in detail, and its analysis, is not only baffling and valueless in my opinion, for medical practice, but may be harmful.

DR. B. SACHS, New York: I would agree with anything of Freud's if I could feel that his teachings were absolutely sound. There are several practical reasons why they do not appeal to me: the first counts least, that is, the length of time the examination takes and the smallness of the result. The most serious objection to the method is that it has had a distinct sexual taint given it. It may be of great interest to the neurologist to find out that some sexual misconception or some disagreeable sexual thought had existed in that person in early years; but, while it may be of great interest to the physician, and while it may not do a woman of 40 any harm to have her psychic analysis made as carefully as Dr. Putnam has performed it, it is my firm conviction that we do no good by taking a young woman of 14 to 20 and pushing her thought back on that one sexual mistake, not a conscious sexual mistake, that was made early in life. I cannot see that the therapeutic results have been any better, nor have they been arrived at any quicker than by the older methods.

DR. C. L. DANA, New York: My practical experience has been not only of failure, but often of disaster with Freud's method. It has often at times been most unfortunate, *and I* have *practically stopped giving any* such treatment in cases of at least the more educated, more intelligent type of patient that comes to me. In the minor cases of this class of psychoneuroses I find that by ordinary methods of treatment, education and modern therapeutics the patients get well. I always tell psychasthenic patients that they will get well, and they generally do. It must be remembered that a certain number of patients run a course, and recover, whether you do anything or not, in one or two years. There is another group of cases, more serious, which date back to early life; these are serious cases. I have not been able to do much with them. If this method will successfully help them, it will be of value, but I do not see exactly how the method could explain or help a condition which is essentially constitutional. The quickest way of getting at the inside of these cases is to do what we practically all try to do and often succeed. I take cases of this kind, put them in a private hospital and give them an intelligent nurse. I go to see them often, and send masseurs whom I know to be intelligent women or men to give them treatment, and by every process that I know of I become acquainted with their story. In two or three weeks one learns about these patients, one knows their past history, and I do not believe you can get as much by the Freud method as by our present method. I think we have much better methods than that of Freud.

Dr. L. F. Barker, Baltimore: Freud's method should be tested carefully. It is too early to say how much good will come of it, but certainly a large amount of new knowledge concerning the psychology of these patients, the psychology of life generally, is being derived from these studies. I think we should separate the method of psychoanalysis from the purely sexual idea. In my application of psychoanalysis it has been very helpful, especially in extending the anamnesis. As to psychasthenic cases, my experience with them is that they are hereditarily badly endowed people. They start badly. Most of them come from generations of neurotic people. I have in mind some cases under my care where for three generations this condition existed. This may come at any time of life, though most of them have attacks early in life.

Dr. C. K. Mills, Philadelphia: I am not in accord with Dr. Putnam's views. *The reports so far have not been altogether* satisfactory. The cures do not seem to be in greater number or better than those obtained by the old methods.

Dr. H. T. Patrick, Chicago: Dr. Putnam's method does not differ so very much from the ordinary methods of psychoanalysis. It seems to me that psychoanalysis, or whatever leads us *to get back to the definite original* cause of any phenomenon in the abnormal patient, or the beginning of what has been the series of abnormal phenomena, is a help. What I believe to be distinctly injurious is to encourage the patient to probe himself when he is by himself, without control and without the leading intelligence of his physician, into his past life *because patients* are unable to observe facts without conclusions, to observe phenomena without interpretation, and it is particularly these neurotic, poorly balanced, hypersensitive people who are constantly drawing wrong conclusions. This is distinctly dangerous, and it is that *particular part of the* Freud method with which I am at variance.

Dr. A. A. Eshner, Philadelphia: These patients are already unduly subjective and introspective, and care should be taken not to make them more so as a result of a certain form of interrogation. Herein appears to reside a *danger* entitled to serious consideration.

Dr. H. N. Moyer, Chicago: I am a disciple of Putnam rather than of Freud. Anyone who undertakes to practice Freud's analysis on his patients on their first visit to the office will soon have no patients. That is obvious. The older methods are to be adhered to for a *certain time*. As to the psychoanalysis of impotence, the physician who neglects to look *for some* prostatic trouble or stricture will probably fail. The old methods are efficient, as a rule, but there is a certain residuum of cases not relieved by ordinary methods and for whom is left this psychoanalysis. It is a *distinct, adequate,* efficient method of getting at a *few* cases that we had not succeeded with before until it was offered to us.

Dr. P. C. Knapp, Boston: There is one radical defect in Freud's general position which has not been touched on. We see almost every day cases of nervous disturbance of one sort or another due clearly and confessedly to some pronounced emotional disturbance. *The patient improves* as the emotional disturbance is put into the background and forgotten. It does not seem always to be a reasonable method of treatment in those cases which are due to a forgotten emotional disturbance to drag that once more into the field and get the patient to dwell on it. It seems to me this is the primary unreasonableness of the views of Freud. *There is a tendency to consider* the data derived from the psychoanalytic methods as being absolutely accurate, but I have not always found them so.

Dr. J. J. Putnam: There is a great deal of misunderstanding of this sexual questioning. One does not take a young unmarried girl and begin to talk about her sexual relations. It would be very extraordinary if anyone should do that. The sexual ideas are the ones that the patient himself brings out. That Freud has always contended. The persons who speak as though the sexual thought were brought out in these patients' minds have failed to recognize that they are suffering from these thoughts, and the purpose is not to dwell on sexual thoughts, but to relieve their minds from sexual thoughts which in another form are active and producing symptoms. As to the objection to the patient's probing himself, it is injurious to him to probe himself alone, and it is to prevent the patient from doing this that the patient is encouraged to probe himself before the physician; the patient probes himself alone from morning to night otherwise, and it is to make it impossible for him to do this that we use this treatment.

General Conception of Dementia Præcox

Dr. Adolf Meyer, New York: The studies of metabolism and toxic state so far furnish nothing specific or decisive in regard to dementia præcox. The neurologic and histologic data appear rather as incidental to more clearly definable functional data than with a leading rôle. The data of conduct and behavior and of reactive material of the patients have proved much more directly helpful in furnishing constructive material. According to the make-up, the same results may be reached by combinations of marked constitutional peculiarity and slight external cause, and slight overt constitutional peculiarities and marked external cause. The essential is the break of *compensation of mental (chiefly emotional and volitional)* adjustment, with more or less deficit—and in most cases with the peculiar attempts at balance and reconstruction which constitute the glaring surface-picture of the clinical description and the special mechanism of the analytical consideration. *Evidence seems to favor the postulate of a departure from* the Kraepelinian dogma. Dementia præcox is essentially unlike general paralysis and more likely the usually inevitable outcome of (1) conflicts of instincts and (2) incapacity for a harmless constructive adjustment.

Some of the Mental Mechanisms in Dementia Præcox

Dr. August Hoch, New York: In certain paranoia states, such as those described by Rüdin and Gaupp, also in a certain type of psychosis recently analyzed by Birnbaum, the content of the psychoses represents conflicts and reactions to conflicts which the individual, owing to a constitutional defect, was incapable of handling adequately. The clinical picture of dementia præcox is much more complicated and often presents apparently a disconnected array of manifestations. When it is possible to analyze these, however, it is found *that* all the experiences mean something to the patient; that certain Freud mechanisms are at work, and that these apparently disconnected symptoms are connected and related *to* definite trends. The frequency with which sexual conflicts are found in the history of such patients and the *fact that so* often sexual trends make up the content of the psychosis, point *to a* lack of sexual adaptation. Our memories are grouped, as it were, in more or less extensive and more or less circumscribed complexes or centers of attraction, *in the* formation and cohesion of which special interests take *an important* part. We can conceive of the *mind, therefore,* as made up essentially of trends of interest. In the course *of* individual development certain main tendencies of the *personality* develop which then take the lead, while other tendencies become repressed. These repressed trends exert nevertheless a marked influence on the conscious thought and activity, as Freud has shown; but in normal life they do so mainly through the fact that the energy they supply is led into profitable channels. Every trend naturally pushes toward a realization in the direction of its feelings. If this is in harmony with the main tendencies of the personality this is useful and represents the dynamic force behind our thinking and our pursuits, adapted to the environment and the given situation. If, however, trends which are not in harmony with the main tendencies of the personality and which are, therefore, under the influences of repression, no longer find an outlet in profitable channels, but assume a more or less independent dominating rôle, it is not to be supposed that the laws which govern normal mental activity should be suspended; on the contrary, we shall expect to find the same principle of the trend pushing toward its realization, while at the same time the other tendencies of the personality assert themselves in repressing influences as well as in adjustment reactions, but owing to the disturbance of balance between the usurping trend and the main tendencies of the personality, the thinking and acting is then no longer adapted to the actual situation, but appears as something strikingly out of contact with it, and is of a simpler, more crude type. This, in so far as the mental side is concerned, is what seems to take place in the cases of dementia præcox which can be analyzed the overgrowth of certain trends at the expense of the main, adapted interests of the personality.

Errors in the Diagnosis of Mental Disease

Dr. E. E. Southard, Boston: A series of 250 cases of mental disease, with *intra vitam* diagnoses by several physicians, recorded at the Danvers State Hospital daily clinics 1904-8, has been subjected to anatomic review for the sake of learning where lies the greatest difficulties in diagnosis. Ten cases (4 per cent.) remain both clinically and anatomically obscure. Seven cases (2.8 per cent.) had diagnostic doubts settled after the clinic, either *intra vitam* or postmortem. Sixty-six cases (26 per cent.) were doubtful clinically, but the correct diagnosis was obtained by one or more diagnosticians in 49 of the 66 (74 per cent. of the doubtful group). One hundred and eighty-four cases (74 per cent.) were clinically certain, and the clinical diagnoses were confirmed (or not altered) by autopsy in 163 of the 184 (89 per cent. of the unanimous group). The correct diagnosis was obtained by one or more diagnosticians in 212 cases in 250 (85 per cent.). The "correctness" of these diagnoses is subject to some reservation, (1) since within the "organic and senile dementia group" differentiation proved difficult, and (2) since anatomic "consistency" often signifies absence of characteristic lesions. The acute psychoses have been reviewed, however, bearing in mind modern views. Several alcoholic cases failed to exhibit striking brain lesions. The majority of the real diagnostic difficulties uncovered by this analysis would appear to require more intensive work in the field of clinical pathology.

The Differentiatives of Dementia Præcox and Depressed States By So-Called Biologic Blood Tests

Drs. E. C. White and S. D. W. Ludlum, Philadelphia: We seem to have been able to differentiate between dementia præcox on the one hand and melancholia on the other. Our method is based on the determination of the fixation complement of guinea-pig serum by the serum of the patient. We found in melancholia that the amount of complement absorbed was very much larger than of all other diseases studied; and also much larger than dementia *præcox*, in which disease it was approximately normal. We have tested 67 cases of various mental diseases. Thirty-seven melancholics of manic-depressive type and involutional forms have so far been decisive and characteristic in all tests. We also found that by carefully standardizing the factors in Much's test it gave a positive test only in dementia præcox. When the standardization was not done, a positive result was often obtained. The syphilitic cases, of course, can be separated by the Wassermann reaction and progress in biologic tests is making it possible to discover chemical changes in so-called functional diseases

Clinical Significance of the Urine in "Nervousness"

Dr. Edward B. Angell, Rochester, N. Y.: I have noted for a number of years in examination of urine of patients afflicted with "nervousness" that in making the Heller nitric acid ring test there is formed at the junction of the urine and acid a pigment ring which varies in color from bright red to dark brown. Of the chemical nature of this ring I am unable to give any account, but believe I am safe in saying that it probably consists of some of the organic nitrogen compounds. It is a reaction entirely different from that given by indican or bile, although these substances may be associated. A similar reaction occurs in cases of exophthalmic goiter and in persons taking iodid of potash. That it is associated with excessive nitrogen elimination is shown by the fact that it is almost never present on a non-proteid diet. The patients who show this reaction are those who complain of headache, backache, restlessness, sleeplessness, numbness and a general depressed feeling, associated with other symptoms generally classed as nervous. If such patients are put on a diet low in nitrogen, lead an open-air life and are given salicylates and alkalies to aid elimination, they will be relieved of their symptoms and at the same time this reaction of the urine will disappear. From two weeks to two months are required for a cure. In obstinate cases a year may be required.

Radiculitis of Cervical and Brachial Plexuses, Secondary to Pachymeningitis Externa Cervicalis-Gummatosa

Dr. F. W. Langdon, Cincinnati: A white man of 33, married, occupation superintending out-door work, grading, etc., gradually developed a paralysis of tetraplegic distribution, beginning in left forearm and hand, and extending in the course of 14 months so as to render useless all four extremities. The upper extremities were flaccid, the lower spastic with plus knee-jerks and Babinski sign. The paralysis was preceded by sharp pains in left neck and face. Neck movements were almost abolished—not by paralysis of muscles, but by articular obstruction. Numbness and tingling were extensively distributed over both arms and legs. A smooth firm, not bony, boss could be felt in the left side of the neck between the third and fourth cervical vertebræ. The patient was unable to walk without constant danger of falling and was unable to grasp a pencil with either hand. Vision was good; pupillary changes slight; ocular movements free, with slight nystagmoid jerking on extreme lateral excursion. Some dysphagia at times. No voice or tongue changes. Sensory changes slight, excepting the initial pain in the left neck and face which was not prominent after the first month. There was a hand-size area of tactile anesthesia over the left thorax and one twice as large over the right abdomen, where temperature sense was disturbed or confused. Diagnosis was made of an exudate (gumma) situated between cervical dura and periosteum enclosing the nerve roots and compressing the lateral columns of cord; a radiculitis and compression myelitis, secondary to pachymeningitis externa. Under mercury by inunction and supporting measures steady improvement occurred and patient was discharged at his own request in five and one-half months, having gained 25 pounds in flesh and the use of all extremities. Three months later he resumed his regular occupation. A year later he is able-bodied, can use pick and shovel well whenever necessary and attends to his full duties in every respect.

The Ocular Changes in General Paresis and Tabes Dorsalis

Dr. Edward D. Fisher, New York: The examination of fifty general paretics confirms my former statement that optic atrophy and ocular muscle paralysis are comparatively rare in general paresis as compared to their frequency in tabes; nor, again, are the muscular paralyses permanent, as a rule. Clinically, this would seem to mark out the two diseases as distinct. In the 50 cases only 2 had optic atrophy and none any third nerve lesion outside of the Argyll-Robertson pupil. In the cerebral type of general paresis, that is, those cases of exaggerated reflexes, the Argyll-Robertson pupil is often absent in the early stages. Among over 200 cases of general paresis only one presented a history of tabes extending over a number of years preceding the mental symptoms with lightning pains, crises and ataxia.

Lenticular Zone and Anarthria

Dr. Alfred Gordon, Philadelphia: A case which I saw shows that Marie's contention in regard to aphasia cannot be entirely confirmed by the pathologic findings. The destruction of the lenticulo-caudate nuclei was complete, and yet the patient did not present the least indication of anarthria or dysarthria. The speech was clear and distinct. The patient did, however, present a partial word-blindness and partial verbal amnesia, all symptoms of sensory aphasia. The few symptoms of the latter correspond to Marie's ideas. The conclusion to which my observation leads me is that while the so-called lenticular zone of Marie may play a certain rôle in sensory aphasia, its rôle is not considerable. As to its being a center for anarthria, the present case proves that its destruction does not interfere with phonation and articulation of words.

Medicolegal

Care, Skill and Diligence Required of Physicians and Surgeons—Malpractice Suit Brought Four Years After Alleged Loss of Eye by Phenol—Burden of Proof and Presumption

The Supreme Court of Alabama says, in Shelton vs. Haeclip (51 So. R. 937), that in McDonald vs. Harris, 131 Ala. 359, the legal measure of care, skill and diligence of physicians and surgeons is thus defined: "The reasonable and ordinary care, skill and diligence which the law requires of physicians and surgeons is such as physicans and surgeons in the same general neighborhood, in the same general line of practice, ordinarily have and exercise in a like case." It was for the alleged breach of this duty that this action was instituted practically four years after the wrong complained of was alleged to have been inflicted. The damnifying result was averred to have been the loss of the eye of the then 11 months old child, Velma Haeclip.

These facts were undisputed on the record: That Velma had been affected with chickenpox and nausea, and the right eye (the one destroyed) was inflamed, ulcerated in the external corner, had scabs on it, and was infected with pus and "septic poison." That the defendant Shelton was called professionally to see her, mainly, it appeared, for the eruption and the nausea. That he examined the right eye, and stated that he would give a prescription for its treatment, and at the same time instructed the parent to keep the organ cleaned with the frequent application of warm boiled water. That what was received as this prescription was used by dropping three or four drops, from a teaspoon, into the eye after lifting the eyelid. That this application was made in the afternoon about 2 o'clock. That the child at once gave evidence of being in great pain in that eye, and, with its hands, rubbed off the scabs and introduced the poisoning pus into the eye. That the sight of the eye was destroyed when examined on the succeeding morning, the destruction being accomplished by the thickening of the tissue over the sight of the eye.

The evident theory of the plaintiff on the trial was that the liquid introduced into the eye contained phenol (carbolic acid), and that the destruction of the sight resulted from that. It was obvious that, if the loss of sight was due to disease, the defendant did not breach his duty, unless in the treatment thereof he failed to measure up to the standard stated before; and it was equally as obvious that the plaintiff's theory excluded any other means or omission leading to that breach of duty in the premises except that rested on the use of phenol in the prescription written by the defendant in the treatment of the eye. A druggist and the defendant both testified that the prescription written by the defendant, was prepared by the druggist, and not by the defendant, and that in it there was no ingredient of phenol. Another physician, who saw the eye the next day, testified that the eye nor lid nor face gave any evidence of having been burned with phenol, and that in his opinion the loss of sight was due to the disease. There were some tendencies in the evidence to the effect that the preparation contained phenol, the chief of which were afforded by the testimony of two witnesses that the contents of the bottle bore an odor of carbolic acid, and that the sediment in the bottom of the bottle was similar to that made by an excess over a solution of phenol.

The burden of proof in cases of this character is on the plaintiff to show that the defendant's care, skill, or diligence in the given case was not that required, as stated, of physicans and surgeons; and it should be added that there is no presumption of negligence or want of skill from the failure to cure.

It is evident from this record that the controlling issue was whether the preparation applied to the eye was that prescribed by the defendant. As indicated, there was some evidence tending to show that the preparation was that prescribed by the defendant, and that it contained phenol. It consisted of the testimony of a Mrs. Daniel, the "next friend," by whom the suit was instituted, that the defendant brought the bottle to the house where the child was, and that out of this bottle, the liquid was put into the eye. It must be conceded, however, that there was a conflict in respect of the issue stated; and, in the light of all the evidence, the court entertains the opinion that the weight of evidence and the probabilities of the truth of that tending to fix liability on the defendant were so strongly against the verdict rendered in the plaintiff's favor as to carry conviction that it was wrong and unjust.

In the first place, the long period of time elapsing between the injury and the institution of the action, in connection with the undisputed fact that the defendant was subsequently often called professionally to treat members of Mrs. Daniel's family, were circumstances impossible to be ignored in determining the weight to be given to Mrs. Daniel's testimony. In the second place, the testimony of a physician who was called as a witness might be taken at the limit of its probative value, and yet, when boiled down, it amounted to nothing more than that the injury "might"—a term, as employed, no stronger than possibly—have been produced by phenol, or "might" (i. e., possibly) have resulted from a virulent form of conjunctivitus. There was for the plaintiff no evidence that the eyeball or its membranes were burned by a caustic. There was a total absence of proof that any sloughing occurred. It is incredible on the evidence adduced as to the effect of phenol that the iris could be altered in color from brown to white by the application of phenol and at the same time avoid sloughing of the cauterized membrane.

The original prescription was before the court. Phenol was not one of its named elements. The other physician first mentioned, who saw the eye the next day, was positive that there was no evidence of cauterization about the eye or face. Two witnesses said there was an odor of phenol, and one that there was a cloudy sediment in the bottle. But the inevitable effect of phenol on membranes and the positive statement of the other physician, apparently disinterested, that there was no cauterization and no sloughing, and the testimony of the druggist and the defendant, all in connection with the long lapse of time between the injury and the commencement of the action and the continuance of the defendant in the professional service of the household, compel the conclusion that phenol did not destroy the child's sight.

Insane Delusions and Unreasonable Habitual Prejudice

The Supreme Court of Illinois says, in the will case of Snell vs. Weldon (90 N. E. R. 1061), that, in analyzing the legal conception of an insane delusion, it is necessary to keep in mind that the ultimate and essential thing to be established is that the testator had, at the time the will or testament was executed, such an aberration as indicates an unsound or deranged condition of the mental faculties, as distinguished from the mere belief in the existence or non-existence of certain supposed facts based on some sort of evidence. A belief which results from a process of reasoning from evidence, however imperfect the process may be or illogical the conclusion, is not an insane delusion. If, under the facts shown, the court is able to see how a rational person might have believed all that the testator believed and still be in the possession of all his senses, an insane delusion is not established. Where a testator has some actual grounds for the belief which he has, though regarded by others as wholly insufficient, the mere misapprehension of the facts or unreasonable and extravagant conclusions drawn therefrom do not establish the existence of such a delusion as will invalidate his will.

Furthermore, while it is true, as said by this court in the former opinion in this case, that "injustice, unfairness, prejudice, or anger without a reasonable cause does not disqualify any person from making a valid will," still, where these manifestations habitually appear in respect to the same subject without any reason, and are adhered to after their falsity is demonstrated, they become strong and satisfactory evidence of a mental derangement, and evidence of their existence, without any cause, in respect to one so nearly related as to be naturally entitled to the testator's bounty, is entitled to greater weight than it would be if the parties were not so closely related.

5. **Treatment of Chorea With Arsenic.**—The authors have employed the Comby-Filatov method with success in four cases. No serious complications occurred, except vomiting in one case and edema of the eyelids and herpes in another. Hassin and Hershfield conclude that arsenious acid in the solution 1:1000 given in smaller doses than advocated by Comby are safer than Fowler's solution. This can be seen from one of these cases where a boy, 8 years of age, could safely bear 5 teaspoonfuls of 1:1000 solution of arsenious acid, i. e., grain 1/3 of arsenious acid, but showed symptoms of intolerance from 9 drops of Fowler's solution and this after his system had been somewhat used to the drug. The time of treatment is considerably shortened by using the acid; the improvement sets in very early, within a few days of treatment, and it is due, exclusively, to the use of arsenic. The authors do not consider it excusable to deprive chorea patients of the benefits of arsenical treatment on account of possible complications. The by-effects of arsenical treatment can be greatly mitigated by using arsenious acid and can be avoided if attention be paid to the condition of the gastro-intestinal and renal apparatuses.

18 *A Method of Examining Sputa for Tubercle Bacilli. E. H. Goodman, Philadelphia.

12. Abstracted in THE JOURNAL, May 28, 1910, p. 1811.

18. **Examination of Sputum for Tubercle Bacilli.**—The solution which Goodman uses is really Labarraque's solution, except that instead of 75 grams chlorinated lime, 150 grams are used, and in addition a solution of 3 per cent. sodium hydroxid. It is to the action of the chlorin and the sodium that its dissolving properties are ascribed. To the sputum is added an equal amount of the solution. The whole is thoroughly mixed with a glass rod, and put on a boiling water bath. After the sputum has become a homogeneous mass (from fifteen to twenty minutes) it is removed from the water bath, a small amount of water added, and the whole is centrifugated for five minutes in an electrically driven centrifuge. If more than one tube is used the supernatant fluid is poured off and the sediments combined, washed in the centrifuge with physiologic salt solution for three to five minutes, the excess poured off, and the residue smeared on a slip by means of a platinum loop. The specimens were stained in the usual manner. Apart from avoiding the necessity of using a patented substance the new solution has the advantage of being about one-fourth as expensive as the former. It is easily made in any laboratory, and where facilities do not permit of this, it may be made by a druggist.

55. **Retention of Foreign Body Below Orbit.**—In adjusting the sight of a Remington rifle, the patient used an enormous charge, about 90 grains of smokeless powder. When the rifle was discharged, it burst open at the breach. The patient received an injury of the face just below the left eye. There was a large gaping wound. It was cleansed and probed by a competent surgeon who decided that there was no foreign body present. The wound was closed and dressed and went on to uneventful recovery. Soon after this the patient began to have what he called a bad catarrhal discharge from the nose. This discharge also would drop into his throat from the nasopharynx. At times it would have a bad odor. Six weeks ago the old wound under the left eye broke open and has been discharging foul pus freely ever since. For years the patient has had double vision. The double vision used to be vertical; now it is horizontal and is worse lately. Ophthalmoscopic examination reveals a congested condition of the retinal veins. The appearance of the nerve head simulates optic neuritis. The general appearance is that of pressure on the optic nerve. The anterior wall of the antrum was freely removed. Far back in the antrum high up, and embedded in the posterior wall was found a foreign body. The tissues around about this were black. On cleaning away the debris the foreign body proved to be a large piece of the steel frame which confines the lock and mechanism of the rifle.

The end of this piece of steel which was deepest embedded was ragged and corroded with rust. The upper edge of the distal end was curved upward and was behind the eyeball. It was necessary, in extracting the steel, to raise the proximal end and depress the distal end in order that it could be extracted without injuring the eyeball.

The floor of the orbit was gone and the soft tissues of the orbit rested on the steel. This steel had penetrated so deeply that the distal end was lodged in the sphenoid bone and had almost entered the cranial cavity. It weighed exactly one ounce.

61. **New Abdominal Gateway.**—Graves makes an incision along the center of the rectus through integument, fascia and the anterior layer of the sheath; then the muscle is displaced outwardly and the incision deepened behind the normal center of the muscle through the remaining structures of the wall, viz., the posterior layer of the sheath, the transversalis fascia, the preperitoneal fat and the peritoneum, or the three latter in the absence of the first. Closure axiomatically is the reverse of the preceding.

70. **Increase of Cancer.**—A great mass of evidence, based on vital statistics, shows a well-marked and steady increase in cancer in practically every civilized country. Attempts to explain away this increase as an apparent and not real increase are far from convincing. Without any further increase the present death-rate from cancer is appalling. Furthermore, the actual death-rate from cancer is much higher than the known rate by reason of the fact that in many cases of patients dying from internal metastases the strong prejudice of the relatives against the name of cancer is respected by the family physician, and some secondary cause of death appears in the certificate, instead of the primary cause, cancer. Deaths from cancer registration area in the United States for 1907 were 30,514 or 1,494 more than in 1906, and a rate of 73.1 in 1907 compared with 70.8 in 1906. Estimated deaths from cancer in the United States for 1907 were 63,508. For the year 1908, 33,465 deaths from this disease were returned, and the death rate was 74.3 per 100,000 of population, as compared with 30,514 deaths and a death rate of 73.1 for 1907.

A careful study of the whole subject shows the increase to be a general one and not limited to a few parts of the body. In other words intra-abdominal or inaccessible cancer, which would be the type most likely to be affected by improved methods of diagnosis, shows even less relative increase than external cancer. In 1868 the death-rate for cancer of the stomach per 1,000,000 living, 35 years and upward, was 283.65 for males and 193.45 for females. In 1888 the rate had increased to 346.15 for males and 277.79 for females, making an increase of 22 per cent. for males and 44 per cent. for females; but in this particular period the death-rate of cancer in general had increased 50 per cent. The greater death-rate of malignant disease in women is due to the large number of cases which occur in the breast and the uterus. In all other localities the liability in the male is much greater than in the female. Cancer has already increased to such an extent that at the present time it causes more deaths among women than tuberculosis, in 1905 the rate being 100 cancer deaths to 94 from tuberculosis. Even taking men and women together, and at all ages, the death-rate from cancer is rapidly approaching that of tuberculosis. From 1851 to 1860 the death-rate per 1,000,000 living was 317 for cancer, 2,676 for phthisis, and 807 for other tuberculous disease; while from 1891 to 1900 the rate was 754 for cancer, 1,391 for phthisis, and 619 for tuberculous diseases.

A careful analysis of the statistics of cancer that are obtainable at the present time forces one to the conclusion that there is a constant and considerable increase in the number of people afflicted with cancer in all civilized countries.

73. **Ligation for Innominate Aneurism.**—DaCosta reports two cases in which this procedure was carried out. One patient is alive and well two and a half years after operation, the other died from some unknown cause three years after the operation.

76. **New Operation for Prominent Ears.**—The operation described by Luckett is for the purpose of reconstructing the fold or truss of the cartilage recognized as the antihelix in ears turned forward, and the same principle is applicable for the reconstruction of the superior crux of the antihelix for the so-called drooping ears, or of both together when necessary. A crescentic incision is made through the integument opposite to the line of the intended new or reconstructed antihelix. The inscribed integument is removed; the edges of the skin are now dissected free from the cartilage and retracted. A similar crescentic segment is removed from the cartilage. The skin and the cartilage are now sutured separately, and it is the method of suturing the cartilage that is emphasized. The cartilage suture is passed from the cranial side from within out and back again, care being taken not to perforate the skin on the external surface, then crossed over the excised portion and passed on the other side from within out and back again as a Lembert suture, in such a manner that when the suture is

drawn tight and tied, not the edges but the sides or flat surfaces of the cartilage will be in apposition. The edges have been turned forward or outward to form the antihelix and at the same time the helix is set closer to the cranium, thus diminishing the cephaloauricular angle. Four or five interrupted sutures are usually enough for the cartilage. The skin is sutured with horsehair. The greatest care must be exercised in asepsis and in the hemostasis. The width of the crescentic segment of the cartilage to be removed depends on the size of the ear, and the thickness of the cartilage.

79. Closure of Abdominal Wounds.—The stitch Norris makes is a quadrilateral one and no matter how tightly it is tied two borders of the quadrangle are unconstricted. A comparatively large area of fascia is brought into apposition and this not only produces firm union but lessens the number of stitches required. As a moderate amount of fascia is taken up with each passage of the needle, and as the stitch is, as it were, a double one, tearing out is extremely unlikely. When the stitch is tied it should form a square each side of which measures about one-fourth of an inch.

96. A New Method of Tying Off Umbilical Cord.—A strip of pure para rubber 7 cm. long, 3 by 3 mm. in cross section, is drawn through a small aluminium ring 7 mm. in diameter, so that a loop 2 cm. long with two free ends is obtained. The one end has a knot fast against the ring and is 7 mm. long, the other end is about 2 cm. long. This constitutes the entire apparatus used by Rothschild. He takes a loop of cord about 5 cm. distal to the umbilicus, places the rubber ligature over it, draws slightly on the end, cuts through the loop, draws the placental end of the cord out, and ties it off as usual. The umbilical end of the cord then has the ligature over it. The ligature is adjusted so that 1½ cm. is on either side of it, then it is drawn tight and remains until the cord "drops off." He has tried it on about 100 cases and with good results. There was no after-bleeding and the cord dropped off normally. It is easy of application, the force exerted is continuous, bleeding cannot take place (it is especially valuable in hemophilia), and costs only a few cents.

100. Diagnosis of Diseases of Sigmoid and Rectum.—Foxworthy describes a specially devised table which he uses for this work. It can be thrown into positions which make possible the proper examination and treatment of these special diseases.

113 Cerebral Localization from the Point of View of Function and Symptoms. M. Prince, Boston.
114* The Sensory Function Attributed to the Seventh Nerve. C. K. Mills, Philadelphia.

114. Sensory Functions of Seventh Nerve.—Mills summarizes his paper as follows: 1. If by the seventh nerve is meant that nerve trunk which arises in the pons from the lower and upper facial nuclei, this nerve is purely motor. 2. It is doubtful whether nerves whose functions are concerned with the pressure and postural senses are conveyed in the branches and trunk of the motor facial. 3. The afferent systems for epicritic and protopathic sensibility are not represented in the seventh nerve. 4. The geniculate ganglion is the homologue of the dorsal spinal ganglia. 5. If the geniculate ganglion, the intermediary nerve of Wrisberg, and the chorda tympani are considered part of the facial or seventh nerve, then this nerve may be regarded as partly sensory, having functions chiefly gustatory. 6. Nerve fibers concerned with the transmission of gustatory impulses proceed from their origin in the geniculate ganglion to their distribution by way of the great superficial petrosal nerve and the chorda tympani. The destination of the former nerve is the soft palate, where its fibers terminate in taste buds, and of the latter nerve the taste buds in the anterior two-thirds of the tongue with the exception of its tip. 7. Evidence is lacking that in the facial trunk proper, in the intermediary nerve of Wrisberg, the great superficial petrosal or the chorda tympani, are nerves of common sensibility, although some observations would seem to indicate that the anterior part of the tongue and possibly a very small strip of the auricle have a vestigial supply of this sort. 8. Herpes does not originate from inflammation of nerves which are not concerned with cutaneous or membranous sensibility. 9. Limited inflammation of the geniculate ganglion may in rare cases occur, producing a syndrome whose factors are loss or perversion of taste and vasodilator and secretory phenomena. 10. If the geniculate ganglion is the seat of inflammation, adjoining parts such as the facial nerve proper, and the eighth nerve may be involved by pressure or extension, thus giving rise to peripheral facial paralysis and to acoustic phenomena and phenomena of equilibration and of orientation, vasodilator and secretory symptoms, or to some of these symptoms. 11. The cases of herpetic inflammation—cervico-occipital, auricular and facial—which have been observed in connection with facial paralysis, or facial paralysis and acoustic symptoms, are best explained on the supposition of an involvement of ganglia other than the geniculate.

129. **Determination of Fat and Fatty Acids.**—Folin and Wentworth determine the fatty acids after extraction by ethereal hydrochloric acid solution, purification of this extract by solution in petroleum ether, and dissolving the residue left after evaporation of ether in benzol, by titration with sodium alcholate, using phenolphthalein as an indicator.

133. **Alkaptonuria.**—Ravold and Warren had the opportunity of examining the urine in a case of alkaptonuria. The fresh urine was clear, from pale yellow to reddish brown, darkening on standing, with no unusual odor. The volume varied from 930 c.c. to 1,425 c.c., averaging, 1,050; the specific gravity varied from 1.009 to 1.016, averaging 1.013. The polariscope showed that it contained no sugar. It was always acid and the fermentation test was negative. It reduced copper solutions only on heating. On contact a black ring appeared but no precipitate, and on mixing the liquids the blue color of the reagent disappeared, the mixture becoming green and beginning to darken from the surface down. It reduced ammoniacal silver solution immediately in the cold, giving a silver mirror on the test tube. It did not reduce alkaline bismuth solutions and gave a negative reaction with the phenylhydrazin test. The uric acid was below the average and the amount of urea seemed to be diminished. The homogentisic acid nitrogen quotient averaged 49.9 which corresponds with that found in other samples of urine containing this substance.

146 *A Simple Differential Stain for Diphtheria Bacilli. D. C. Ragland, Los Angeles.

146. **Differential Stain for Diphtheria Bacilli.**—Ragland has devised the following stain intended specially for the "small town" physician who has a microscope but no incubator. The stain is made up of methylene blue and eosin and the adult diphtheria bacillus is quickly recognized because the polar granules are stained a deep blue, while the remaining portion of the bacillus takes the eosin or pink stain, making thereby a decided contrast. The stain is composed of three solutions, the formula and technic for using which are as follows: Solution "A": Methylene blue, saturated aqueous solution, 10 parts; 10 per cent. citric acid solution, 10 parts; aqua destillata, 80 parts. Solution "B": 10 per cent. aqueous solution citric acid, 5 parts; methyl alcohol, 22 parts; distilled water 73 parts. Solution "C": Eosin, saturated aqueous solution, 1 part; aqua destillata, 199 parts.

The technic is as follows: 1. Make thin smears from throat, especially from the margin of membrane or suspicious path. 2. Dry in air. 3. Fix in flame (gas or alcohol). 4. Add sufficient blue stain "A" to cover smear and allow to act 10 to 15 seconds; then shake it off but do not wash. Now apply solution "B" and allow to act for 10 to 15 seconds, then shake it off, but do not wash. Lastly add solution "C" and allow it to act for 10 to 15 seconds; then shake off excess of stain and blot dry with filter or blotting paper, mount in Canada balsam or cedar oil and examine. Diphtheria bacilli show as pink rods with a dark blue granule in either pole. All other bacilli and cocci are stained pink. This stain has been controlled by the culture method of laboratory diagnosis in over 1,000 cases.

159 Abscess of Liver in an Eight-year-old Boy: Operation. J. R. Judd, Honolulu, H. I.

152. **Substitute Feeding in Premature Infants.**—Ladd studied these cases in two hospitals. In one hospital there were included in this series 95 babies of whom 58, or 61 per cent., died; 24, or 25.3 per cent., lived and gained in weight; 13, or 13.7 per cent., lived but were discharged, either losing in weight or making no gain. Of the last mentioned group many were taken home because of their condition, and probably died, so that the ultimate mortality was undoubtedly considerably more than 61 per cent. In the other hospital there were 30 babies included in the series. Of these, 24 died, giving a mortality of 80 per cent., and 6 lived and gained in weight, a percentage of 20. The mortality was therefore nearly 20 per cent. greater at the Children's Hospital than at the Infants' Hospital. This difference is probably accounted for by the fact that no infant was discharged while losing in weight and condition. All were allowed to remain in the wards until their condition warranted treatment at home.

The total mortality was 65.6 per cent. in 118 out of 125 babies weighing under 2,100 grams at birth. No infant weighing under 1,200 at birth survived. No infant in the sixth month of gestation survived. The smallest baby admitted weighed 570 grams and lived six days. The possibility of materially lowering the mortality by providing proper means of conveying premature infants to the hospital is very great. Premature babies who survived gained on an average only 50 grams a week on modified milk, for an average period of 70 days each. The average energy quotient of the food of 11 patients who lived and gained in weight was 107. There was no definite relation between the energy quotient of the food and the weekly gain in weight. Modified milk, however, carefully administered and supervised, must be considered an unsatisfactory food for premature infants. and should be used only when breast milk cannot be obtained. Ladd says that hospitals planning to receive premature infants should make ample provision for the maintenance of wet nurses. The relative value of padded cribs and incubators could not be accurately judged, as modern incubators have not been used at either of the two hospitals in which this study was made.

153. **Acidified Milk in Pediatric Practice.**—Brady believes from his experience that acidified milk fills a long felt want in the institution feeding of infants. Pure air, however, is indispensable, and the larger the ward and the fewer babies in that ward the greater the success with any method of feeding. Young infants at birth may with advantage be placed on this food. Thrush and other forms of stomatitis are seldom met with in infants receiving this food. The development of scurvy and rickets need never be feared. Acidified milk places at the disposal of the infant the casein in the form of the lactate, which is so necessary for the growth and development of the infant in an assimilable form and in a sufficient quantity. The lactic acid bacillus and the lactic acid certainly seem to prevent the development of intestinal indigestion, as the babies on this food almost invariably have good stools. It seems that the infant, when receiving acidified milk mixtures is in a better position to care for the fats, and that a larger percentage of fat may be fed than when on the usual modified milk mixtures. The casein in acidified milk being in the form of the lactate is not affected by the rennin. Brady emphasizes the rarity of curds in the stools of infants receiving acidified milk mixtures even when top milk mixtures are employed, but he does not advise the use of these high fat percentages in the early weeks, as fat diarrhea and fat intoxication must be reckoned with. From his observations it would seem that fat alone, and protein alone, are not responsible for the curds in the stools of infants fed on cows' milk; for their production it would seem that the fats require the presence of the proteins and that with both acting together the result is the very familiar curdy, mucous stool; the latter due to a secondary catarrh from the irritation of the former. This reasoning seems close at hand when it is considered what occurs in acidified milk feeding. The proteins are in the form of very fine particles, especially if the acidified milk has been well agitated, not coagulable by rennin; therefore, its deleterious influence on the fats is removed, and hence the normal stools. In order to be successful in feeding acidified milk, it is necessary to be well grounded in the principles of infant feeding, and this method does not furnish a short route to this goal. The good results seem due not alone to the low fat, to the presence of lactic acid and to the chemical change of the protein, but the presence of the lactic acid bacillus plays a very definite rôle.

In private practice cases of malnutrition, intestinal indigestion and diarrhea should have this food. Finally, Brady would make a special plea that the city infant during the days of excessive heat, the latter part of July and August especially, receive the advantage of this food.

157. **Clean Milk.**—In the 13 years, from 1884 to 1897, inclusive, during which no systematic milk work was done in Rochester, the total number of deaths under one year of age was 6,306, and the deaths between one and five years of age, 3,304, making a total of deaths from birth to five years of age, 9,610. For the 13 year period, from 1897 to 1909, inclusive, the total deaths under one year of age were 4,641, and the deaths from one to five years of age 2,080, making a total of 6,721. In the first period not all of the deaths were reported; in the last period we have reported the death of every child born at term who breathed. The mortality between birth and five years of age showed a diminution of 30 per cent. in the last period. This, Goler shows, is what can be done when the baby gets clean milk.

7 *The Treatment of the Partially Drowned. J. A. Barnes.

7. **Treatment of the Partially Drowned.**—The result to be aimed at in the treatment of such persons, says Barnes, is the driving of the blood from the abdomen, so that the brain may receive its proper supply. This he aims at by an attempt at auto-transfusion as follows: Having started an assistant on artificial respiration, he firmly bandages the legs from the feet upward. A roller towel is then passed around the patient's abdomen, the two ends crossing in front. One assistant is told off to each of these ends. As the arms are brought down to the chest in the expiratory movement of artificial respiration (Silvester's method) these two assistants grasping the towel-ends firmly with their right hands, pull them, at the same time making pressure on the abdomen with their left hands. In this way considerable squeezing of the abdomen is obtained. As the inspiratory movement commences the pressure is relaxed so as not to interfere with the expansion of the lungs. The process is continued synchronously with the movements of artificial respiration. Barnes' idea is that this acts beneficially in two ways: (1) it assists, by pressing up the diaphragm, to more completely empty the chest with expiration; and (2) it squeezes some of the excess of blood from the abdominal cavity. The bandaging of the legs and arrangement of the towel can be very quickly carried out with assistance, of which there is usually no lack in these cases.

Gravity should also be made to assist the flow of blood to the brain by keeping the head at a lower level than the body. He gives a hypodermic injection of ether (30 minims) and usually one of strychnin as well. The objection to the use of these stimulants—that they stimulate an already tired center and are quickly followed by increasing depression—seems hardly to apply in cases of drowning, as when once reaction has set in recovery is usually rapid.

32 The Heart (concluded). S. West.
33 The Hyperemic Treatment of Inflammation. A. V. Poyser.

28. Tumors of the Tongue.—The two cases of endothelioma of the tongue reported by Eve presented many features in common. In each the growth occupied the extreme base of the tongue and formed a very prominent disk-shaped mass which was not ulcerated on the surface. Glands were distinctly enlarged in the superior carotid triangle in both. The symptoms had been discomfort or a feeling of a foreign body in the fauces, and were so slight that the growth attained a considerable size before it was discovered. The microscopic character of the tumor in the first case was of a lymph-endotheliomatous type, the growths consisting of cord-like masses of endothelial cells, in places surrounding dilated lymphatic channels. In the second case it was peritheliomatous. There were very numerous and large vascular channels surrounded by cords of endothelial cells. The third case was one of epithelioma.

38 Poisoning by Sulphate of Zinc. A. Palmer.

37. Strangulated Hernia in an Infant.—Sixteen days after birth, the baby was suddenly seized with an attack of vomiting and seemed very ill. Then it got a little better and passed some urine and feces. An hour later Moule found a lump in the upper part of the right scrotum; neither nurse nor mother had noticed it. The lump gurgled on pressure, but was irreducible even under chloroform. The sac when opened proved to be a patent funicular process containing about four inches of purplish gut.

43 *Polioencephalitis of the Cerebello-Rubrospinal System—A Cause of "Acute Tremor" in Children. L. Parsons.
44 *A Model Crèche. B. Myers.

43. Polioencephalitis.—While polioencephalitis will not account for all forms of acute tremor, for it has been seen associated with a tuberculous tumor, Parsons holds that a diagnosis of polioencephalitis can usually be made by a consideration of the type and age of the child, the season of the year, character of the onset, and the course of the disease, the absence of changes in the fundi oculorum and cerebrospinal fluid, and in those cases where it does occur, the presence of an associated poliomyelitis.

44. A Modern Crèche.—The ideal, or modern crèche, Myers says, should be so arranged (a) that the day nurseries, bathrooms, etc., for the children's use ought to be on the ground floor; (b) that the kitchen scullery, larder, pantry, mother's dining-room, and a laundry-room should be situated in the basement; and (c) that the matron's and nurses' bedrooms, sitting room, students' room, cloak-room, etc., could be conveniently placed on the first floor.

50 Subphrenic Abscess Complicating Pregnancy with Sloughing of Spleen. B. A. J. Solomons.

47. After-Results in Abdominal Operations.—A review of the final results in 248 cases has convinced Giles that the effect of hysteropexy on the general health is very good, as 90 per cent. of the patients were better than before the operation, as many as 75 per cent. being in quite good health; while among the 10 per cent. who were not better the cause had nothing to do with the operation in one-half of them. Symptoms are markedly relieved; 90 per cent. of the patients had either no pain afterward or had less pain than before the operation; 14 patients were relieved of dysmenorrhea, 21 of dyspareunia, and 16 of headaches; 22 patients got relief from menorrhagia, and 13 from excessive leucorrhea; 13 patients found their constipation improved. As regards the effect of hysteropexy on the bladder, 18 per cent. of patients experienced frequency of micturition, and 77 per cent. had no trouble, or no more than before operation. The position of the uterus remains permanently good in about 95 per cent. of cases; about 5 per cent. suffer from partial or complete return of displacement. The results in cases of procidentia are not quite as good as in cases of retroversion or prolapse; but 88 per cent. of cases of procidentia show permanent good results. To obtain the best results in the latter cases combined operations are usually necessary. In the event of pregnancy following hysteropexy, there is a slightly increased tendency to miscarriage if pregnancy follows too soon after the operation; hysteropexy causes no subsequent complications of labor, as out of 44 cases of full-time delivery 40 had normal confinements, and the remaining 4 had complications independent of the operation. When pregnancy follows hysteropexy, the position of the uterus is not disturbed thereby, as the results after pregnancy were just as good as in cases where no pregnancy followed, and the cases of full-time delivery showed only one case of partial return of displacement out of 29 cases. Among these cases, therefore, the uterus kept in good position in 96.6 per cent. of the cases, as against 94.7 per cent. in the cases of patients who did not become pregnant.

49. Red Degeneration of Fibroids.—Murray examined four specimens of red degeneration of uterine fibroids and found that the lipoids of degenerating fibroids are markedly hemolytic. This hemolytic action is readily restrained by blood plasma. Excess of lipoid in a suspension of red blood corpuscles leads to the development of a gray or brown color in place of the red. Thrombosis in red degeneration is not primary. Red degeneration microscopically is indentical with certain other degenerating fibroids showing no red. The accumulation of lipoid is not, in the first instance, dependent on the presence or amount of thrombosis, but on the degree of preceding degeneration. Laking of the corpuscles has more relation to lack of the fluid constituents of the blood than to large excess of lipoid. Many of the stains in fibroids—not necessarily red stains—may be due to old symptomless hemolysis.

51 *Chronic Appendicitis in Children. J. Comby.
52 Vital Staining with Neutral Red for Study of the Pathologic Cerebrospinal Fluid. E. Weill and A. Policard.

51. **Chronic Appendicitis in Children.**—Comby reviews 31 operative cases and 108 others in which chronic appendicitis was diagnosed, and discusses the differential signs. The condition is more common than generally recognized, he says; many cases of assumed dyspepsia, anemia, chlorosis, liver affections, enterocolitis, the status lymphaticus and tuberculosis are in reality solely or mainly the effect of chronic appendicitis. Acute appendicitis is generally merely the flaring up of a chronic process, and physicians should be on the lookout for this. Periodical vomiting is a sign that the child is a candidate for acute appendicitis, as also a tendency to repeated indigestion. Constipation is habitual and obstinate although diarrhea may be observed; some of the children fail to develop properly but after removal of the appendix grow promptly to normal stature. There is also, he says, a nervous form of chronic appendicitis. Children with it are moody, disinclined to play or work, and seek solitude. A change of character in this line, and discovery of digestive disturbances should suggest chronic appendicitis. Intercostal neuralgia may also be a sign, or pain in the right leg, with a tendency to limp, suggesting hip or knee disease; Comby has had several cases of this kind. In another group the suggestive symptom was a tendency to faint, the children growing pale and falling in syncope but retaining consciousness throughout. Headache, convulsions, urticaria and prurigo were observed in other cases. The proof in regard to the causal appendicitis in these cases is afforded by the rapid restoration to normal after appendicectomy. A spontaneous cure of chronic appendicitis cannot be counted on, although there may be symptomless intervals, sometimes of years. Surgical treatment is required in the majority of cases, especially for chronic appendicitis in children. The dangers of an interval operation are so slight as to be negligible, but the diagnosis must be positive. In case of doubt he prefers to operate and has never yet had occasion to regret his decision.

56 *Inflammation and Thickening of the Pleura with Persistent Effusion. (Les pachypleurites et les pleurésies intarissables.) M. Dieulafoy.

June 11, No. 47, pp. 433-440

57 Sudden Variations in the Number of Leucocytes Depending on the Arterial Pressure. J. Camus and P. Pagniez.

53-56. **Pleurisy with Persistent Effusion.**—Dieulafoy reports two cases of thickening of the pleura with recurring effusion for ten years in one case and for twenty years in the other. The patients were tapped over a hundred times and a total of over 230 liters was withdrawn but the general health persisted constantly excellent; the patients were incommoded merely by the mechanical disturbance from the effusion. In the first case the effusion was purulent and fetid and streptococci and pneumobacilli could be cultivated from it, but they were of such attenuated virulence that they proved harmless for animals. In the other case the effusion was constantly sterile. The effusion in both cases has finally ceased, the patients not having required tapping for a long time. Dieulafoy theoretically advocates decortication of the lung in such cases, but there was nothing to indicate that active intervention was necessary in these or in a third case in which the patient was tapped 15 times in the course of six years; there has been no return of the effusion since 1885 in this last case.

54. **Vomiting of Pregnancy.**—Pinard gives a historical review of this subject and states that years of experience have confirmed him more and more in the conviction that intoxication is responsible for the tendency of pregnant women to vomit, and that the outcome depends on the intensity of the intoxication. He reiterates his assertion that the pulse is the best index of the degree of intoxication, and that if it goes above 100 the pregnancy should be interrupted at once. The details of 7 recent cases are added to supplement the 20 he has previously published (reviewed in THE JOURNAL, Oct. 30, 1909, page 1518).

55. **Inflammatory Tuberculosis of Internal Genitals.**—Poncet and Leriche regard a latent tuberculosis as responsible in many cases for sclerosis of the ovaries or toxic impregnation of the Graafian follicles entailing infantilism, hypoplasia of the genitals, amenorrhea, dysmenorrhea, pelvic neuralgia or a tendency to abortions. An old chronic latent tuberculous process may likewise explain the heavy, easily bleeding, painful uterus in women of the alleged neuroarthritic type. All require general antituberculosis measures and possibly tuberculin.

Revue de Chirurgie, Paris

June, XXX, No. 6, pp. 967-1174

58 *Disadvantages of Scopolamin for General Anesthesia. (Chloroforme. Chloral. Scopolamine.) P. Delbet and R. Dupont.
59 Later Results of Transplantation of Veins on Arteries. A. Carrel.

61 Tumors of the Jaws of Dental Origin. (Enclavomes dentaires.) R. Leriche and G. Cotte.
62 Rôle and Mechanism of Infectious Disturbances from a Wisdom Tooth. (Accidents de dent de sagesse.) C. Capdepont.

58. **Disadvantages of Scopolamin for General Anesthesia.**—Delbet and Dupont review their experiences with 120 patients given a dose of scopolamin as a preliminary to chloroform. The list includes 2 fatalities, one serious postoperative syncope and a number of other mishaps. They refer also to Flateau's one fatality in 30 cases, Ziffler's 3 in 64 cases and Blos' several serious mishaps and one death in 105 cases. They declare that the advantages ascribed to the use of scopolamin for this purpose are more apparent than real; it may retard vomiting but does not do away with it altogether. Scopolamin, they add, is unquestionably toxic for patients whose emunctories are out of order, even in a dose as small as 0.001 gm. (1/64 grain). They express a decided preference for chloral as a preliminary to chloroform, as it is not dangerous and in the dose of 4 gm. (61 grains) tranquillizes the patient and prevents the phase of agitation under chloroform. They have used it thus in 850 cases, giving the chloral in water about half an hour before the operation. In the 22 cases on record of fatalities following an injection of scopolamin as a preliminary to general anesthesia, 13 were cancer patients. This proportion warns especially against giving scopolamin to patients with cancer. In 4 other cases the surgical affection was in the neck. In one of the other cases an unusually large dose of scopolamin had been given (0.0036 gm. scopolamin and 0.06 gm. morphin).

Semaine Médicale, Paris

63 *Subacute Typhoid Septicemia. V. Audibert.

June 15, No. 24, pp. 277-288

64 *Dilatation of the Stomach Owing to a Lesion in the Peritoneum or Stomach Wall. J. Paviot.

63. **Subacute Typhoid Septicemia.**—Audibert declares that sufficient attention has not been paid to subacute septicemia from the typhoid bacillus, and yet it is extremely common. The reaction to the presence of the bacillus in the blood may vary with every individual attacked. He protests against restricting the idea of typhoid toxi-infection to the syndrome involving the intestine; it may attack any organ

or tissue and the syndrome has probably many times been diagnosed as influenza, atypical typhoid, gastric fever, etc. This subacute "Eberthian septicemia" has a slow onset; there is no uniform type of fever but it may long continue, with gastric disturbances; the mind is not affected and the patient feels calm and wants to eat. He thinks that this form of typhoid infection occurs more commonly in children than the typical form.

64. **Dilatation of the Stomach from Lesions in the Wall or Peritoneum.**—Paviot has examined with the microscope the stomach from certain cases of dilatation during life and found invariably some lesion in the wall or peritoneum, evidently responsible for the dilatation—of course this material excludes all cases of stenosis of the pylorus. The lesion may long have healed, but it leaves the stomach wall more or less insufficient for its task, owing to sclerosis in the region adjoining the lesion. Careful inquiry will generally elicit a history of some inflammatory process in the region, possibly years before. Once convinced that these dilated stomachs, painful at times or with recurring pains, are of inflammatory nature, wonderful benefit may be derived from energetic revulsion or similar therapeutic procedures, entirely aside from dietetic measures. It may even be advanced as a principle that the more the dilatation of the stomach seems to coincide with painful points in the region below the liver or in the right flank, the better the prospects of a cure under heat and revulsion applied perseveringly to the painful zones. Local revulsion may also prove useful with other gastric disturbances, as for instance for a hard drinker with ulcerative gastritis or a patient with hematemesis and the epigastrium more or less tender; the benefit derived in some of these cases from heat or blisters is another argument in favor of the inflammatory origin of dilatation of the stomach in some cases, whether secondary to inflammation in the peritoneum or to gastric ulcer.

70 *Nervous Dyspepsia. A. Bofinger.
71 Influence of the Salicylates, Mercury and Certain other Drugs on the Diastase Content of the Saliva. (Zur Kenntnis der diastatischen Wirkung des menschlichen Mundspeichels.) (Einfluss einiger Medikamente auf die Speicheldiastase.) E. Fricker. Commenced in No. 2.

65. **Salt Content of Common Articles of Food.**—Leva's research in this line was mentioned with some of his conclusions in The Journal, July 2, page 93. His tables fill over 15 pages, presenting the results of over 360 analyses and comparing them with those of others. The work has been done to supply a basis for a systematic salt-poor or salt-free diet but he does not here discuss the indications for either.

69. Summarized in The Journal, April 23, 1910, page 1405.

70. **Nervous Dyspepsia.**—Bofinger reviews the various conflicting views on this subject and advocates classifying in three groups the stomach symptoms generally described under the name of nervous dyspepsia: 1, those of neurogenic origin, that is, disturbances occurring peripherally in the organ, from disease or trauma, irritation with centripetal conduction—this is the neurasthenic type; 2, the central or psychogenic type with centrifugal conduction of the irritation to the organ—the hysteric type; and 3, those of central, psychogenic origin but with no conduction of the irritation—the hypochrondriac type. These types are frequently combined and various observers interpret the symptoms in different fashion according to their pet theories. In a case described in detail the syndrome was accompanied by all the signs of Stiller's universal asthenia, also of what Cramer calls chronic atony of the intestines, while the patient could also be regarded as an example of Strümpell's axiom: "It is not the stomach trouble that makes a man a hypochondriac; it is the hypochondria that entails the stomach trouble." The patient, a young bachelor, further presented attacks of sudden dyspnea, with a chill, pain in the heart region, irregular pulse, etc., the attacks lasting perhaps half an hour—a typical example of what M. Herz has described as the *sexual psychogenic* cardiac neurosis. Each one of these scientists might have ticketed and demonstrated the case exclusively as a typical example of his special assumption in regard to nervous dyspepsia.

79 Röntgenology in the Service of the General Practitioner. G. Loose.

72. **Determination of Invisible Blood.**—Citron examines the fluid in question by mixing with alcohol, then rinsing with ether and dissolving the residue in pyridin. The latter dissolves the blood pigments and they are readily detected with the spectroscope if the specimen is inspected through its longest diameter. He uses a square shallow chamber to hold the specimen and examines it lengthwise.

75. **The Pneumatic Cabinet in Treatment of Chronic Bronchitis.**—Samter refers in particular to bronchitis associated with cardiac insufficiency and tabulates the effect on the blood pressure of the therapeutic application of the pneumatic cabinet. The influence of the compressed air is felt in the promotion of the respiration; the diaphragm descends deeper, the lungs expand, the walls of the bronchi spread apart and the mucus clinging to them is carried out by the more vigorous respiration. The best results were obtained with chronic bronchial catarrh without much fluid secretion. His experience has shown that even with a weak heart musculature the blood pressure does not drop in the cabinet, confirming the harmlessness of the method in uncomplicated cases of cardial bronchitis.

76. **Treatment of Paralysis of the Arm.**—Helbing discusses the orthopedic management of spastic cerebral hemiplegia and birth paralysis, emphasizing the importance of over-stretching of the muscle as the cause of the trouble. When the ends of the muscle are brought closer together, correcting the over-stretching, the apparently paralyzed muscle will often regain its function as he shows by some typical examples.

80 *Artificial Feeding of New-born Infants. (Zur Kenntnis der künstlichen Ernährung Neugeborener.) E. Döbeli.

80. **Infant Feeding.**—Döbeli gives artificial food to a new-born infant only in amounts sufficient to keep the child at the same weight after the first physiologic decline. He is convinced that the child brings with it into the world enough reserves to supply the needed calories for a time with little assistance. It has been his experience that children with the "exudative diathesis" were rather above the normal weight at birth, and he has never witnessed any harm result from keeping the food down to 300 gm. for the first two days and 500 or 600 gm. for the two or three weeks following. He prefers a 25 per cent. dilution of milk, generally skimmed. The children thrive better when kept on this small amount for the first few weeks. Plump children especially are well supplied with a reserve of calories and do not need to have fat supplied in the food at first.
